

Package ‘GenomicRanges’

October 12, 2016

Title Representation and manipulation of genomic intervals and variables defined along a genome

Description The ability to efficiently represent and manipulate genomic annotations and alignments is playing a central role when it comes to analyzing high-throughput sequencing data (a.k.a. NGS data). The GenomicRanges package defines general purpose containers for storing and manipulating genomic intervals and variables defined along a genome. More specialized containers for representing and manipulating short alignments against a reference genome, or a matrix-like summarization of an experiment, are defined in the GenomicAlignments and SummarizedExperiment packages respectively. Both packages build on top of the GenomicRanges infrastructure.

Version 1.24.3

absoluteRanges	<i>Transform genomic ranges into "absolute" ranges</i>
----------------	--

Description

absoluteRanges transforms the genomic ranges in `x` into *absolute* ranges i.e. into ranges counted from the beginning of the virtual sequence obtained by concatenating all the sequences in the underlying genome (in the order reported by `seqlevels(x)`).

relativeRanges performs the reverse transformation.

NOTE: These functions only work on *small* genomes. See Details section below.

Usage

```
absoluteRanges(x)
relativeRanges(x, seqlengths)
```

```
## Related utility:
isSmallGenome(seqlengths)
```

Arguments

<code>x</code>	For absoluteRanges: a GenomicRanges object with ranges defined on a <i>small</i> genome (see Details section below). For relativeRanges: a Ranges object.
<code>seqlengths</code>	An object holding sequence lengths. This can be a named integer (or numeric) vector with no duplicated names as returned by seqlengths() , or any object from which sequence lengths can be extracted with seqlengths() . For relativeRanges, seqlengths must describe a <i>small</i> genome (see Details section below).

Details

Because absoluteRanges returns the *absolute* ranges in an [IRanges](#) object, and because an [IRanges](#) object cannot hold ranges with an end $> .Machine$integer.max$ (i.e. $\geq 2^{31}$ on most platforms), absoluteRanges cannot be used if the size of the underlying genome (i.e. the total length of the sequences in it) is $> .Machine$integer.max$. Utility function isSmallGenome is provided as a mean for the user to check upfront whether the genome is *small* (i.e. its size is $\leq .Machine$integer.max$) or not, and thus compatible with absoluteRanges or not.

relativeRanges applies the same restriction by looking at the seqlengths argument.

Value

An [IRanges](#) object for absoluteRanges.

A [GRanges](#) object for relativeRanges.

isSmallGenome returns TRUE if the total length of the underlying sequences is $\leq .Machine$integer.max$ (e.g. Fly genome), FALSE if not (e.g. Human genome), or NA if it cannot be computed (because some sequence lengths are NA).

Examples

```
## -----
## TOY EXAMPLE
## -----

gr <- GRanges(Rle(c("chr2", "chr1", "chr3", "chr1"), 4:1),
              IRanges(1:10, width=5),
              seqinfo=Seqinfo(c("chr1", "chr2", "chr3"), c(100, 50, 20)))

ar <- absoluteRanges(gr)
ar

gr2 <- relativeRanges(ar, seqlengths(gr))
gr2

## Sanity check:
stopifnot(all(gr == gr2))

## -----
## ON REAL DATA
## -----

## With a "small" genome

library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
ex <- exons(txdb)
ex

isSmallGenome(ex)

## Note that because isSmallGenome() can return NA (see Value section
## above), its result should always be wrapped inside isTRUE() when
## used in an if statement:
if (isTRUE(isSmallGenome(ex))) {
  ar <- absoluteRanges(ex)
  ar

  ex2 <- relativeRanges(ar, seqlengths(ex))
  ex2 # original strand is not restored

  ## Sanity check:
```

```

    strand(ex2) <- strand(ex) # restore the strand
    stopifnot(all(ex == ex2))
}

## With a "big" genome (but we can reduce it)

library(TxDb.Hsapiens.UCSC.hg19.knownGene)
txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
ex <- exons(txdb)
isSmallGenome(ex)
## Not run:
    absoluteRanges(ex) # error!

## End(Not run)

## However, if we are only interested in some chromosomes, we might
## still be able to use absoluteRanges():
seqlevels(ex, force=TRUE) <- paste0("chr", 1:10)
isSmallGenome(ex) # TRUE!
ar <- absoluteRanges(ex)
ex2 <- relativeRanges(ar, seqlengths(ex))

## Sanity check:
strand(ex2) <- strand(ex)
stopifnot(all(ex == ex2))

```

Description

Attaching a Constraint object to an object of class A (the "constrained" object) is meant to be a convenient/reusable/extensible way to enforce a particular set of constraints on particular instances of A.

THIS IS AN EXPERIMENTAL FEATURE AND STILL VERY MUCH A WORK-IN-PROGRESS!

Details

For the developer, using constraints is an alternative to the more traditional approach that consists in creating subclasses of A and implementing specific validity methods for each of them. However, using constraints offers the following advantages over the traditional approach:

- The traditional approach often tends to lead to a proliferation of subclasses of A.
- Constraints can easily be re-used across different classes without the need to create any new class.
- Constraints can easily be combined.

All constraints are implemented as concrete subclasses of the Constraint class, which is a virtual class with no slots. Like the Constraint virtual class itself, concrete Constraint subclasses cannot have slots.

Here are the 7 steps typically involved in the process of putting constraints on objects of class A:

1. Add a slot named `constraint` to the definition of class A. The type of this slot must be `ConstraintORNULL`. Note that any subclass of A will inherit this slot.
2. Implements the `constraint()` accessors (getter and setter) for objects of class A. This is done by implementing the `"constraint"` method (getter) and replacement method (setter) for objects of class A (see the examples below). As a convenience to the user, the setter should also accept the name of a constraint (i.e. the name of its class) in addition to an instance of that class. Note that those accessors will work on instances of any subclass of A.
3. Modify the validity method for class A so it also returns the result of `checkConstraint(x, constraint(x))` (append this result to the result returned by the validity method).
4. Testing: Create `x`, an instance of class A (or subclass of A). By default there is no constraint on it (`constraint(x)` is `NULL`). `validObject(x)` should return `TRUE`.
5. Create a new constraint (`MyConstraint`) by extending the `Constraint` class, typically with `setClass("MyConstraint", contains="Constraint")`. This constraint is not enforcing anything yet so you could put it on `x` (with `constraint(x) <- "MyConstraint"`), but not much would happen. In order to actually enforce something, a `"checkConstraint"` method for signature `c(x="A", constraint="MyConstraint")` needs to be implemented.
6. Implement a `"checkConstraint"` method for signature `c(x="A", constraint="MyConstraint")`. Like validity methods, `"checkConstraint"` methods must return `NULL` or a character vector describing the problems found. Like validity methods, they should never fail (i.e. they should never raise an error). Note that, alternatively, an existing constraint (e.g. `SomeConstraint`) can be adapted to work on objects of class A by just defining a new `"checkConstraint"` method for signature `c(x="A", constraint="SomeConstraint")`. Also, stricter constraints can be built on top of existing constraints by extending one or more existing constraints (see the examples below).
7. Testing: Try `constraint(x) <- "MyConstraint"`. It will or will not work depending on whether `x` satisfies the constraint or not. In the former case, trying to modify `x` in a way that breaks the constraint on it will also raise an error.

Note

WARNING: This note is not true anymore as the constraint slot has been temporarily removed from `GenomicRanges` objects (starting with package `GenomicRanges` \geq 1.7.9).

Currently, only `GenomicRanges` objects can be constrained, that is:

- they have a `constraint` slot;
- they have `constraint()` accessors (getter and setter) for this slot;
- their validity method has been modified so it also returns the result of `checkConstraint(x, constraint(x))`.

More classes in the `GenomicRanges` and `IRanges` packages will support constraints in the near future.

```
## The examples below show how to define and set constraints on
## GenomicRanges objects. Note that this is how the constraint()
## setter is defined for GenomicRanges objects:
#setReplaceMethod("constraint", "GenomicRanges",
#  function(x, value)
#    {
#      if (isSingleString(value))
#        value <- new(value)
#      if (!is(value, "ConstraintORNULL"))
#        stop("the supplied 'constraint' must be a ",
#             "Constraint object, a single string, or NULL")
#      x@constraint <- value
#      validObject(x)
#      x
#    }
#)

#selectMethod("constraint", "GenomicRanges") # the getter
#selectMethod("constraint<-", "GenomicRanges") # the setter

## We'll use the GRanges instance 'gr' created in the GRanges examples
## to test our constraints:
example(GRanges, echo=FALSE)
gr
#constraint(gr)

## -----
## EXAMPLE 1: The HasRangeTypeCol constraint.
## -----
## The HasRangeTypeCol constraint checks that the constrained object
## has a unique "rangeType" metadata column and that this column
## is a 'factor' Rle with no NAs and with the following levels
## (in this order): gene, transcript, exon, cds, 5utr, 3utr.

setClass("HasRangeTypeCol", contains="Constraint")

## Like validity methods, "checkConstraint" methods must return NULL or
## a character vector describing the problems found. They should never
## fail i.e. they should never raise an error.
setMethod("checkConstraint", c("GenomicRanges", "HasRangeTypeCol"),
  function(x, constraint, verbose=FALSE)
  {
    x_mcols <- mcols(x)
```

```

    idx <- match("rangeType", colnames(x_mcols))
    if (length(idx) != 1L || is.na(idx)) {
      msg <- c("'mcols(x)' must have exactly 1 column ",
              "named \"rangeType\"")
      return(paste(msg, collapse=""))
    }
    rangeType <- x_mcols[[idx]]
    .LEVELS <- c("gene", "transcript", "exon", "cds", "5utr", "3utr")
    if (!is(rangeType, "Rle") ||
        S4Vectors:::anyMissing(runValue(rangeType)) ||
        !identical(levels(rangeType), .LEVELS))
    {
      msg <- c("'mcols(x)$rangeType' must be a ",
              "'factor' Rle with no NAs and with levels: ",
              paste(.LEVELS, collapse=", "))
      return(paste(msg, collapse=""))
    }
    NULL
  }
)

#\dontrun{
#constraint(gr) <- "HasRangeTypeCol" # will fail
#}
checkConstraint(gr, new("HasRangeTypeCol")) # with GenomicRanges >= 1.7.9

levels <- c("gene", "transcript", "exon", "cds", "5utr", "3utr")
rangeType <- Rle(factor(c("cds", "gene"), levels=levels), c(8, 2))
mcols(gr)$rangeType <- rangeType
#constraint(gr) <- "HasRangeTypeCol" # OK
checkConstraint(gr, new("HasRangeTypeCol")) # with GenomicRanges >= 1.7.9

## Use is() to check whether the object has a given constraint or not:
#is(constraint(gr), "HasRangeTypeCol") # TRUE
#\dontrun{
#mcols(gr)$rangeType[3] <- NA # will fail
#}
mcols(gr)$rangeType[3] <- NA
checkConstraint(gr, new("HasRangeTypeCol")) # with GenomicRanges >= 1.7.9

## -----
## EXAMPLE 2: The GeneRanges constraint.
## -----
## The GeneRanges constraint is defined on top of the HasRangeTypeCol
## constraint. It checks that all the ranges in the object are of type
## "gene".

setClass("GeneRanges", contains="HasRangeTypeCol")

## The checkConstraint() generic will check the HasRangeTypeCol constraint
## first, and, only if it's satisfied, it will then check the GeneRanges
## constraint.
setMethod("checkConstraint", c("GenomicRanges", "GeneRanges"),

```

```

function(x, constraint, verbose=FALSE)
{
  rangeType <- mcols(x)$rangeType
  if (!all(rangeType == "gene")) {
    msg <- c("all elements in 'mcols(x)$rangeType' ",
            "must be equal to \"gene\"")
    return(paste(msg, collapse=""))
  }
  NULL
}
)

#\dontrun{
#constraint(gr) <- "GeneRanges" # will fail
#}
checkConstraint(gr, new("GeneRanges")) # with GenomicRanges >= 1.7.9

mcols(gr)$rangeType[] <- "gene"
## This replace the previous constraint (HasRangeTypeCol):
#constraint(gr) <- "GeneRanges" # OK
checkConstraint(gr, new("GeneRanges")) # with GenomicRanges >= 1.7.9

#is(constraint(gr), "GeneRanges") # TRUE
## However, 'gr' still indirectly has the HasRangeTypeCol constraint
## (because the GeneRanges constraint extends the HasRangeTypeCol
## constraint):
#is(constraint(gr), "HasRangeTypeCol") # TRUE
#\dontrun{
#mcols(gr)$rangeType[] <- "exon" # will fail
#}
mcols(gr)$rangeType[] <- "exon"
checkConstraint(gr, new("GeneRanges")) # with GenomicRanges >= 1.7.9

## -----
## EXAMPLE 3: The HasGCCol constraint.
## -----
## The HasGCCol constraint checks that the constrained object has a
## unique "GC" metadata column, that this column is of type numeric,
## with no NAs, and that all the values in that column are >= 0 and <= 1.

setClass("HasGCCol", contains="Constraint")

setMethod("checkConstraint", c("GenomicRanges", "HasGCCol"),
  function(x, constraint, verbose=FALSE)
  {
    x_mcols <- mcols(x)
    idx <- match("GC", colnames(x_mcols))
    if (length(idx) != 1L || is.na(idx)) {
      msg <- c("'mcols(x)' must have exactly ",
              "one column named \"GC\"")
      return(paste(msg, collapse=""))
    }
    GC <- x_mcols[[idx]]
  }
)

```

```

    if (!is.numeric(GC) ||
        S4Vectors:::anyMissing(GC) ||
        any(GC < 0) || any(GC > 1))
    {
      msg <- c("'mcols(x)$GC' must be a numeric vector ",
              "with no NAs and with values between 0 and 1")
      return(paste(msg, collapse=""))
    }
    NULL
  }
)

## This replace the previous constraint (GeneRanges):
#constraint(gr) <- "HasGCCol" # OK
checkConstraint(gr, new("HasGCCol")) # with GenomicRanges >= 1.7.9

#is(constraint(gr), "HasGCCol") # TRUE
#is(constraint(gr), "GeneRanges") # FALSE
#is(constraint(gr), "HasRangeTypeCol") # FALSE

## -----
## EXAMPLE 4: The HighGCRanges constraint.
## -----
## The HighGCRanges constraint is defined on top of the HasGCCol
## constraint. It checks that all the ranges in the object have a GC
## content >= 0.5.

setClass("HighGCRanges", contains="HasGCCol")

## The checkConstraint() generic will check the HasGCCol constraint
## first, and, if it's statisfied, it will then check the HighGCRanges
## constraint.
setMethod("checkConstraint", c("GenomicRanges", "HighGCRanges"),
  function(x, constraint, verbose=FALSE)
  {
    GC <- mcols(x)$GC
    if (!all(GC >= 0.5)) {
      msg <- c("all elements in 'mcols(x)$GC' ",
              "must be >= 0.5")
      return(paste(msg, collapse=""))
    }
    NULL
  }
)

#\dontrun{
#constraint(gr) <- "HighGCRanges" # will fail
#}
checkConstraint(gr, new("HighGCRanges")) # with GenomicRanges >= 1.7.9
mcols(gr)$GC[6:10] <- 0.5
#constraint(gr) <- "HighGCRanges" # OK
checkConstraint(gr, new("HighGCRanges")) # with GenomicRanges >= 1.7.9

```

```

#is(constraint(gr), "HighGCRanges") # TRUE
#is(constraint(gr), "HasGCCol") # TRUE

## -----
## EXAMPLE 5: The HighGCCGeneRanges constraint.
## -----
## The HighGCCGeneRanges constraint is the combination (AND) of the
## GeneRanges and HighGCRanges constraints.

setClass("HighGCCGeneRanges", contains=c("GeneRanges", "HighGCRanges"))

## No need to define a method for this constraint: the checkConstraint()
## generic will automatically check the GeneRanges and HighGCRanges
## constraints.

#constraint(gr) <- "HighGCCGeneRanges" # OK
checkConstraint(gr, new("HighGCCGeneRanges")) # with GenomicRanges >= 1.7.9

#is(constraint(gr), "HighGCCGeneRanges") # TRUE
#is(constraint(gr), "HighGCRanges") # TRUE
#is(constraint(gr), "HasGCCol") # TRUE
#is(constraint(gr), "GeneRanges") # TRUE
#is(constraint(gr), "HasRangeTypeCol") # TRUE

## See how all the individual constraints are checked (from less
## specific to more specific constraints):
#checkConstraint(gr, constraint(gr), verbose=TRUE)
checkConstraint(gr, new("HighGCCGeneRanges"), verbose=TRUE) # with
                                                                # GenomicRanges
                                                                # >= 1.7.9

## See all the "checkConstraint" methods:
showMethods("checkConstraint")

```

coverage-methods

Coverage of a GRanges or GRangesList object

Description

[coverage](#) methods for [GRanges](#) and [GRangesList](#) objects.

NOTE: The [coverage](#) generic function and methods for [Ranges](#) and [RangesList](#) objects are defined and documented in the [IRanges](#) package. Methods for [GAlignments](#) and [GAlignmentPairs](#) objects are defined and documented in the [GenomicAlignments](#) package.

Usage

```

## S4 method for signature 'GenomicRanges'
coverage(x, shift=0L, width=NULL, weight=1L,
         method=c("auto", "sort", "hash"))

```

```
## S4 method for signature 'GRangesList'
coverage(x, shift=0L, width=NULL, weight=1L,
         method=c("auto", "sort", "hash"))
```

Arguments

x	A GRanges or GRangesList object.
shift	A numeric vector or a list-like object. If numeric, it must be parallel to x (recycled if necessary). If a list-like object, it must have 1 list element per seqlevel in x, and its names must be exactly <code>seqlevels(x)</code> . Alternatively, <code>shift</code> can also be specified as a single string naming a metadata column in x (i.e. a column in <code>mcols(x)</code>) to be used as the <code>shift</code> vector. See ?coverage in the IRanges package for more information about this argument.
width	Either NULL (the default), or an integer vector. If NULL, it is replaced with <code>seqlengths(x)</code> . Otherwise, the vector must have the length and names of <code>seqlengths(x)</code> and contain NAs or non-negative integers. See ?coverage in the IRanges package for more information about this argument.
weight	A numeric vector or a list-like object. If numeric, it must be parallel to x (recycled if necessary). If a list-like object, it must have 1 list element per seqlevel in x, and its names must be exactly <code>seqlevels(x)</code> . Alternatively, <code>weight</code> can also be specified as a single string naming a metadata column in x (i.e. a column in <code>mcols(x)</code>) to be used as the <code>weight</code> vector. See ?coverage in the IRanges package for more information about this argument.
method	See ?coverage in the IRanges package for a description of this argument.

Details

When x is a [GRangesList](#) object, `coverage(x, ...)` is equivalent to `coverage(unlist(x), ...)`.

Value

A named [RleList](#) object with one coverage vector per seqlevel in x.

Author(s)

H. Pagès and P. Aboyoun

- [coverage-methods](#) in the **GenomicAlignments** package.
- [RleList](#) objects in the **IRanges** package.
- [GRanges](#) and [GRangesList](#) objects.

Examples

```
## Coverage of a GRanges object:
gr <- GRanges(
  seqnames=Rle(c("chr1", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
  ranges=IRanges(1:10, end=10),
  strand=Rle(strand(c("-", "+", "*+", "+", "-")), c(1, 2, 2, 3, 2)),
  seqlengths=c(chr1=11, chr2=12, chr3=13))
cvg <- coverage(gr)
pcvg <- coverage(gr[strand(gr) == "+"])
mcvg <- coverage(gr[strand(gr) == "-"])
scvg <- coverage(gr[strand(gr) == "*"])
stopifnot(identical(pcvg + mcvg + scvg, cvg))

## Coverage of a GRangesList object:
gr1 <- GRanges(seqnames="chr2",
  ranges=IRanges(3, 6),
  strand = "+")
gr2 <- GRanges(seqnames=c("chr1", "chr1"),
  ranges=IRanges(c(7,13), width=3),
  strand=c("+", "-"))
gr3 <- GRanges(seqnames=c("chr1", "chr2"),
  ranges=IRanges(c(1, 4), c(3, 9)),
  strand=c("-", "-"))
grl <- GRangesList(gr1=gr1, gr2=gr2, gr3=gr3)
stopifnot(identical(coverage(grl), coverage(unlist(grl))))
```

DelegatingGenomicRanges-class

DelegatingGenomicRanges objects

Description

The DelegatingGenomicRanges class implements the virtual GenomicRanges class using a delegate GenomicRanges. This enables developers to create GenomicRanges subclasses that add specialized columns or other structure, while remaining agnostic to how the data are actually stored. See the Extending GenomicRanges vignette.

Author(s)

M. Lawrence

 findOverlaps-methods *Finding overlapping genomic ranges*

Description

Various methods for finding/counting overlaps between objects containing genomic ranges. This man page describes the methods that operate on [GenomicRanges](#) and [GRangesList](#) objects.

NOTE: The [findOverlaps](#) generic function and methods for [Ranges](#) and [RangesList](#) objects are defined and documented in the **IRanges** package. The methods for [GAlignments](#), [GAlignmentPairs](#), and [GAlignmentsList](#) objects are defined and documented in the **GenomicAlignments** package.

[GenomicRanges](#) and [GRangesList](#) objects also support `countOverlaps`, `overlapsAny`, and `subsetByOverlaps` thanks to the default methods defined in the **IRanges** package and to the `findOverlaps` and `countOverlaps` methods defined in this package and documented below.

Usage

```
## S4 method for signature 'GenomicRanges,GenomicRanges'
findOverlaps(query, subject,
             maxgap=0L, minoverlap=1L,
             type=c("any", "start", "end", "within", "equal"),
             select=c("all", "first", "last", "arbitrary"),
             ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
countOverlaps(query, subject,
             maxgap=0L, minoverlap=1L,
             type=c("any", "start", "end", "within", "equal"),
             ignore.strand=FALSE)
```

Arguments

`query`, `subject` A [GRanges](#) or [GRangesList](#) object.

`maxgap`, `minoverlap`, `type`
See [findOverlaps](#) in the **IRanges** package for a description of these arguments.

`select` When `select` is "all" (the default), the results are returned as a [Hits](#) object. Otherwise the returned value is an integer vector parallel to `query` (i.e. same length) containing the first, last, or arbitrary overlapping interval in `subject`, with NA indicating intervals that did not overlap any intervals in `subject`.

`ignore.strand` When set to TRUE, the strand information is ignored in the overlap calculations.

Details

When the `query` and the `subject` are [GRanges](#) or [GRangesList](#) objects, `findOverlaps` uses the triplet (sequence name, range, strand) to determine which features (see paragraph below for the definition of feature) from the `query` overlap which features in the `subject`, where a strand value of "*" is treated as occurring on both the "+" and "-" strand. An overlap is recorded when a

feature in the query and a feature in the subject have the same sequence name, have a compatible pairing of strands (e.g. `"+"/"+"`, `"-"/"-"`, `"*"/"+"`, `"*"/"-"`, etc.), and satisfy the interval overlap requirements.

In the context of `findOverlaps`, a feature is a collection of ranges that are treated as a single entity. For `GRanges` objects, a feature is a single range; while for `GRangesList` objects, a feature is a list element containing a set of ranges. In the results, the features are referred to by number, which run from 1 to `length(query)/length(subject)`.

Value

For `findOverlaps` either a `Hits` object when `select="all"` or an integer vector otherwise.

For `countOverlaps` an integer vector containing the tabulated query overlap hits.

Author(s)

P. Aboyoun, S. Falcon, M. Lawrence, and H. Pagès

 GenomicRanges-comparison

Comparing and ordering genomic ranges

Description

Methods for comparing and ordering the elements in one or more [GenomicRanges](#) objects.

Usage

```
## duplicated()
## -----

## S4 method for signature 'GenomicRanges'
duplicated(x, incomparables=FALSE, fromLast=FALSE,
           method=c("auto", "quick", "hash"))

## match() & selfmatch()
## -----

## S4 method for signature 'GenomicRanges,GenomicRanges'
match(x, table, nomatch=NA_integer_, incomparables=NULL,
      method=c("auto", "quick", "hash"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
selfmatch(x, method=c("auto", "quick", "hash"), ignore.strand=FALSE)

## order() and related methods
## -----

## S4 method for signature 'GenomicRanges'
is.unsorted(x, na.rm=FALSE, strictly=FALSE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
order(..., na.last=TRUE, decreasing=FALSE, method=c("shell", "radix"))

## S4 method for signature 'GenomicRanges'
sort(x, decreasing=FALSE, ignore.strand=FALSE, by)

## S4 method for signature 'GenomicRanges'
rank(x, na.last=TRUE,
     ties.method=c("average", "first", "random", "max", "min"))

## Generalized parallel comparison of 2 GenomicRanges objects
## -----

## S4 method for signature 'GenomicRanges,GenomicRanges'
```

```
pcompare(x, y)
```

Arguments

<code>x, table, y</code>	GenomicRanges objects.
<code>incomparables</code>	Not supported.
<code>fromLast, method, nomatch</code>	See <code>?`Ranges-comparison`</code> in the IRanges package for a description of these arguments.
<code>ignore.strand</code>	Whether or not the strand should be ignored when comparing 2 genomic ranges.
<code>na.rm</code>	Ignored.
<code>strictly</code>	Logical indicating if the check should be for <i>strictly</i> increasing values.
<code>...</code>	One or more GenomicRanges objects. The GenomicRanges objects after the first one are used to break ties.
<code>na.last</code>	Ignored.
<code>decreasing</code>	TRUE or FALSE.
<code>ties.method</code>	A character string specifying how ties are treated. Only "first" is supported for now.
<code>by</code>	An optional formula that is resolved against <code>as.env(x)</code> ; the resulting variables are passed to <code>order</code> to generate the ordering permutation.

Details

Two elements of a [GenomicRanges](#) object (i.e. two genomic ranges) are considered equal iff they are on the same underlying sequence and strand, and have the same start and width. `duplicated()` and `unique()` on a [GenomicRanges](#) object are conforming to this.

The "natural order" for the elements of a [GenomicRanges](#) object is to order them (a) first by sequence level, (b) then by strand, (c) then by start, (d) and finally by width. This way, the space of genomic ranges is totally ordered. Note that the `reduce` method for [GenomicRanges](#) uses this "natural order" implicitly. Also, note that, because we already do (c) and (d) for regular ranges (see `?`Ranges-comparison``), genomic ranges that belong to the same underlying sequence and strand are ordered like regular ranges.

`is.unsorted()`, `order()`, `sort()`, and `rank()` on a [GenomicRanges](#) object behave accordingly to this "natural order".

`==`, `!=`, `<=`, `>=`, `<` and `>` on [GenomicRanges](#) objects also behave accordingly to this "natural order".

Author(s)

H. Pagès, `is.unsorted` contributed by Pete Hickey

GenomicRangesList-class

GenomicRangesList objects

Description

A `GenomicRangesList` is a [List](#) of [GenomicRanges](#). It is a virtual class; `SimpleGenomicRangesList` is the basic implementation. The subclass `GRangesList` provides special behavior and is particularly efficient for storing a large number of elements.

Constructor

`GenomicRangesList(...)`: Constructs a `SimpleGenomicRangesList` with elements taken from the arguments in `...`. If the only argument is a list, the elements are taken from that list.

Coercion

`as(from, "GenomicRangesList")`: Supported from types include:

RangedDataList Each element of from is coerced to a GenomicRanges.
 as(from, "RangedDataList"): Supported from types include:

GenomicRangesList Each element of from is coerced to a RangedData.

Author(s)

Michael Lawrence

See Also

[GRangesList](#), which differs from SimpleGenomicRangesList in that the GRangesList treats its elements as single, compound ranges, particularly in overlap operations. SimpleGenomicRangesList is just a barebones list for now, without that compound semantic.

genomicvars

Manipulating genomic variables

Description

A *genomic variable* is a variable defined along a genome. Here are 2 ways a genomic variable is generally represented in Bioconductor:

1. as a named [RleList](#) object with one list element per chromosome;
2. as a metadata column on a *disjoint* GRanges object.

This man page documents tools for switching from one form to the other.

Usage

```
bindAsGRanges(...)
mcolAsRleList(x, varname)
binnedAverage(bins, numvar, varname)
```

Arguments

...	One or more genomic variables in the form of named RleList objects.
x	A <i>disjoint</i> GRanges object with metadata columns on it. A GRanges object is said to be <i>disjoint</i> if it contains ranges that do not overlap with each other. This can be tested with <code>isDisjoint</code> . See <code>?`isDisjoint,GenomicRanges-method`</code> for more information about the <code>isDisjoint</code> method for GRanges objects.
varname	The name of the genomic variable. For <code>mcolAsRleList</code> this must be the name of the metadata column on x to be turned into an RleList object. For <code>binnedAverage</code> this will be the name of the metadata column that contains the binned average in the returned object.
bins	A GRanges object representing the genomic bins. Typically obtained by calling tileGenome with <code>cut.last.tile.in.chrom=TRUE</code> .
numvar	A named RleList object representing a numerical variable defined along the genome covered by bins (which is the genome described by <code>seqinfo(bins)</code>).

Details

`bindAsGRanges` allows to switch the representation of one or more genomic variables from the *named RleList* form to the *metadata column on a disjoint GRanges object* form by binding the supplied named `RleList` objects together and putting them on the same `GRanges` object. This transformation is lossless.

`mcolAsRleList` performs the opposite transformation and is also lossless (however the circularity flags and genome information in `seqinfo(x)` won't propagate). It works for any metadata column on `x` that can be put in `Rle` form i.e. that is an atomic vector or a factor.

`binnedAverage` computes the binned average of a numerical variable defined along a genome.

Value

For `bindAsGRanges`: a `GRanges` object with 1 metadata column per supplied genomic variable.

For `mcolAsRleList`: a named `RleList` object with 1 list element per `seqlevel` in `x`.

For `binnedAverage`: the `GRanges` object bins with an additional metadata column named `varname` containing the binned average.

Author(s)

H. Pagès

See Also

- `coverage,GenomicRanges-method` for computing the coverage of a `GRanges` object.
- The `tileGenome` function for putting tiles on a genome.
- `GRanges` objects and `isDisjoint,GenomicRanges-method` for the `isDisjoint` method for `GenomicRanges` objects.

Examples

```
## -----
## A. TWO WAYS TO REPRESENT A GENOMIC VARIABLE
## -----

## 1) As a named RleList object
## -----
## Let's create a genomic variable in the "named RleList" form:
library(BSgenome.Scerevisiae.UCSC.sacCer2)
set.seed(55)
my_var <- RleList(
  lapply(seqlengths(Scerevisiae),
    function(seqlen) {
      tmp <- sample(50L, seqlen, replace=TRUE)
      Rle(cumsum(tmp - rev(tmp)))
    }
  ),
  compress=FALSE)
```

```

my_var

## 2) As a metadata column on a disjoint GRanges object
## -----
gr1 <- bindAsGRanges(my_var=my_var)
gr1

gr2 <- GRanges(c("chrI:1-150",
                 "chrI:211-285",
                 "chrI:291-377",
                 "chrV:51-60"),
              score=c(0.4, 8, -10, 2.2),
              id=letters[1:4],
              seqinfo=seqinfo(Scerevisiae))
gr2

## Going back to the "named RleList" form:
mcolAsRleList(gr1, "my_var")
score <- mcolAsRleList(gr2, "score")
score
id <- mcolAsRleList(gr2, "id")
id
bindAsGRanges(score=score, id=id)

## Bind 'my_var', 'score', and 'id' together:
gr3 <- bindAsGRanges(my_var=my_var, score=score, id=id)

## Sanity checks:
stopifnot(identical(my_var, mcolAsRleList(gr3, "my_var")))
stopifnot(identical(score, mcolAsRleList(gr3, "score")))
stopifnot(identical(id, mcolAsRleList(gr3, "id")))
gr2b <- bindAsGRanges(score=score, id=id)
seqinfo(gr2b) <- seqinfo(gr2)
stopifnot(identical(gr2, gr2b))

## -----
## B. BIND TOGETHER THE COVERAGES OF SEVERAL BAM FILES
## -----

library(pasillaBamSubset)
library(GenomicAlignments)
untreated1_cvg <- coverage(BamFile(untreated1_chr4()))
untreated3_cvg <- coverage(BamFile(untreated3_chr4()))
all_cvg <- bindAsGRanges(untreated1=untreated1_cvg,
                        untreated3=untreated3_cvg)

## Keep regions with coverage:
all_cvg[with(mcols(all_cvg), untreated1 + untreated3 >= 1)]

## Plot the coverage profiles with the Gviz package:
library(Gviz)
plotNumvars <- function(numvars, region, name="numvars", ...)
{

```

```

stopifnot(is(numvars, "GRanges"))
stopifnot(is(region, "GRanges"), length(region) == 1L)
gtrack <- GenomeAxisTrack()
dtrack <- DataTrack(numvars,
                    chromosome=as.character(seqnames(region)),
                    name=name,
                    groups=colnames(mcols(numvars)), type="1", ...)
plotTracks(list(gtrack, dtrack), from=start(region), to=end(region))
}
plotNumvars(all_cvgs, GRanges("chr4:1-25000"),
            "coverage", col=c("red", "blue"))
plotNumvars(all_cvgs, GRanges("chr4:1.03e6-1.08e6"),
            "coverage", col=c("red", "blue"))

## Sanity checks:
stopifnot(identical(untreated1_cvgs, mcolAsRleList(all_cvgs, "untreated1")))
stopifnot(identical(untreated3_cvgs, mcolAsRleList(all_cvgs, "untreated3")))

## -----
## C. COMPUTE THE BINNED AVERAGE OF A NUMERICAL VARIABLE DEFINED ALONG A
## GENOME
## -----

## In some applications (e.g. visualization), there is the need to compute
## the average of a genomic variable for a set of predefined fixed-width
## regions (sometimes called "bins").
## Let's use tileGenome() to create such a set of bins:
bins1 <- tileGenome(seqinfo(Scerevisiae), tilewidth=100,
                    cut.last.tile.in.chrom=TRUE)

## Compute the binned average for 'my_var' and 'score':
bins1 <- binnedAverage(bins1, my_var, "binned_var")
bins1
bins1 <- binnedAverage(bins1, score, "binned_score")
bins1

## Binned average in "named RleList" form:
binned_var1 <- mcolAsRleList(bins1, "binned_var")
binned_var1
stopifnot(all.equal(mean(my_var), mean(binned_var1))) # sanity check

mcolAsRleList(bins1, "binned_score")

## With bigger bins:
bins2 <- tileGenome(seqinfo(Scerevisiae), tilewidth=50000,
                    cut.last.tile.in.chrom=TRUE)
bins2 <- binnedAverage(bins2, my_var, "binned_var")
bins2 <- binnedAverage(bins2, score, "binned_score")
bins2

binned_var2 <- mcolAsRleList(bins2, "binned_var")
binned_var2
stopifnot(all.equal(mean(my_var), mean(binned_var2))) # sanity check

```

```
mcolAsRleList(bins2, "binned_score")

## Not surprisingly, the "binned" variables are much more compact in
## memory than the original variables (they contain much less runs):
object.size(my_var)
object.size(binned_var1)
object.size(binned_var2)
```

GNCList-class

GNCList objects

Description

The GNCList class is a container for storing the Nested Containment List representation of a vector of genomic ranges (typically represented as a [GRanges](#) object). To preprocess a [GRanges](#) object, simply call the GNCList constructor function on it. The resulting GNCList object can then be used for efficient overlap-based operations on the genomic ranges.

Usage

```
GNCList(x)
```

Arguments

x The [GRanges](#) (or more generally [GenomicRanges](#)) object to preprocess.

Details

The [IRanges](#) package also defines the [NCList](#) and [NCLists](#) constructors and classes for preprocessing and representing a [Ranges](#) or [RangesList](#) object as a data structure based on Nested Containment Lists.

Note that GNCList objects (introduced in BioC 3.1) are replacements for GIntervalTree objects (BioC < 3.1).

See [?NCList](#) in the [IRanges](#) package for some important differences between the new algorithm based on Nested Containment Lists and the old algorithm based on interval trees. In particular, the new algorithm supports preprocessing of a [GenomicRanges](#) object with ranges defined on circular sequences (e.g. on the mitochondrial chromosome). See below for some examples.

Value

A GNCList object.

Author(s)

H. Pagès

References

Alexander V. Alekseyenko and Christopher J. Lee – Nested Containment List (NCList): a new algorithm for accelerating interval query of genome alignment and interval databases. *Bioinformatics* (2007) 23 (11): 1386-1393. doi: 10.1093/bioinformatics/btl647

See Also

- The [NCList](#) and [NCLists](#) constructors and classes defined in the [IRanges](#) package.
- [findOverlaps](#) for finding/counting interval overlaps between two *range-based* objects.
- [GRanges](#) objects.

Examples

```
## The examples below are for illustration purpose only and do NOT
## reflect typical usage. This is because, for a one time use, it is
## NOT advised to explicitly preprocess the input for findOverlaps()
## or countOverlaps(). These functions will take care of it and do a
## better job at it (by preprocessing only what's needed when it's
## needed, and release memory as they go).

## -----
## PREPROCESS QUERY OR SUBJECT
## -----

query <- GRanges(Rle(c("chrM", "chr1", "chrM", "chr1"), 4:1),
                 IRanges(1:10, width=5), strand=rep(c("+", "-"), 5))
subject <- GRanges(Rle(c("chr1", "chr2", "chrM"), 3:1),
                  IRanges(6:1, width=5), strand="+")

## Either the query or the subject of findOverlaps() can be preprocessed:

ppsobject <- GNCList(subject)
hits1a <- findOverlaps(query, ppsobject)
hits1a
hits1b <- findOverlaps(query, ppsobject, ignore.strand=TRUE)
hits1b

ppquery <- GNCList(query)
hits2a <- findOverlaps(ppquery, subject)
hits2a
hits2b <- findOverlaps(ppquery, subject, ignore.strand=TRUE)
hits2b

## Note that 'hits1a' and 'hits2a' contain the same hits but not
## necessarily in the same order.
stopifnot(identical(sort(hits1a), sort(hits2a)))
## Same for 'hits1b' and 'hits2b'.
stopifnot(identical(sort(hits1b), sort(hits2b)))

## -----
## WITH CIRCULAR SEQUENCES
```

```
## -----
seqinfo <- Seqinfo(c("chr1", "chr2", "chrM"),
                  seqlengths=c(100, 50, 10),
                  isCircular=c(FALSE, FALSE, TRUE))
seqinfo(query) <- seqinfo[seqlevels(query)]
seqinfo(subject) <- seqinfo[seqlevels(subject)]

ppsobject <- GNCList(subject)
hits3 <- findOverlaps(query, ppsobject)
hits3

## Circularity introduces more hits:

stopifnot(all(hits1a %in% hits3))
new_hits <- setdiff(hits3, hits1a)
new_hits # 1 new hit
query[queryHits(new_hits)]
subject[subjectHits(new_hits)] # positions 11:13 on chrM are the same
                               # as positions 1:3

## Sanity checks:
stopifnot(identical(new_hits, Hits(9, 6, 10, 6, sort.by=query=TRUE)))
ppquery <- GNCList(query)
hits4 <- findOverlaps(ppquery, subject)
stopifnot(identical(sort(hits3), sort(hits4)))
```

GPos-class

GPos objects

Description

The GPos class is a container for storing a set of genomic *positions*, that is, genomic ranges of width 1. Even though a [GRanges](#) object can be used for that, using a GPos object can be much more memory-efficient, especially when the object contains long runs of adjacent positions.

Usage

```
GPos(pos_runs) # constructor function
```

Arguments

`pos_runs` A [GRanges](#) object (or any other [GenomicRanges](#) derivative) where each range is interpreted as a run of adjacent genomic positions. If `pos_runs` is not a [GenomicRanges](#) object, `GPos()` first tries to coerce it to one with `as(pos_runs, "GenomicRanges", strict=FALSE)`.

Value

A GPos object.

Accessors

Getters: GPos objects support the same set of getters as [GRanges](#) objects (i.e. `seqnames()`, `start()`, `end()`, `ranges()`, `strand()`, `mcols()`, `seqinfo()`, etc...), plus the `pos()` getter which is equivalent to `start()` or `end()`. See `?GRanges` for the list of getters supported by [GRanges](#) objects.

Note that a GPos object cannot hold names i.e. `names()` always returns NULL on it.

Setters: Like [GRanges](#) objects, GPos objects support the following setters:

- The `mcols()` and `metadata()` setters.
- The family of setters that operate on the `seqinfo` component of an object: `seqlevels()`, `seqlevelsStyle()`, `seqlengths()`, `isCircular()`, `genome()`, and `seqinfo()`. These setters are defined and documented in the **GenomeInfoDb** package.

However, there is no `seqnames()`, `pos()`, or `strand()` setter for GPos objects at the moment (although they might be added in the future).

Coercion

From [GenomicRanges](#) to GPos: A [GenomicRanges](#) object `x` in which all the ranges have a width of 1 can be coerced to a GPos object with `as(x, "GPos")`. The names on `x` are not propagated (a warning is issued if `x` has names on it).

From GPos to [GRanges](#): A GPos object `x` can be coerced to a [GRanges](#) object with `as(x, "GRanges")`. However be aware that the resulting object can use thousands times (or more) memory than `x`! See "MEMORY USAGE" in the Examples section below.

From GPos to ordinary R objects: Like with a [GRanges](#) object, `as.character()`, `as.factor()`, and `as.data.frame()` work with a GPos object `x`. Note that `as.data.frame(x)` returns a data frame with a `pos` column (containing `pos(x)`) instead of the `start`, `end`, and `width` columns that one gets when `x` is a [GRanges](#) object.

Subsetting

A GPos object can be subsetted exactly like a [GRanges](#) object.

Combining

GPos objects can be combined (a.k.a. appended) with `c()` or `append()`.

Splitting and Relisting

Like with a [GRanges](#) object, `split()` and `relist()` work with a GPos object `x`. Note that they return a [GenomicRangesList](#) object instead of a [GRangesList](#) object.

Note

Like for any [Vector](#) derivative, the length of a GPos object cannot exceed `.Machine$integer.max` (i.e. 2^{31} on most platforms). `GPos()` will return an error if `pos_runs` contains too many genomic positions.

Examples

```
## -----
## BASIC EXAMPLES
## -----

## Example 1:
gpos1 <- GPos(c("chr1:44-53", "chr1:5-10", "chr2:2-5"))
gpos1

length(gpos1)
seqnames(gpos1)
pos(gpos1) # same as 'start(gpos1)' and 'end(gpos1)'
strand(gpos1)
as.character(gpos1)
as.data.frame(gpos1)
as(gpos1, "GRanges")
as.data.frame(as(gpos1, "GRanges"))
gpos1[9:17]

## Example 2:
pos_runs <- GRanges("chrI", IRanges(c(1, 6, 12, 17), c(5, 10, 16, 20)),
                    strand=c("+", "-", "-", "+"))
gpos2 <- GPos(pos_runs)
gpos2

strand(gpos2)

## Example 3:
gpos3A <- gpos3B <- GPos(c("chrI:1-1000", "chrI:1005-2000"))
npos <- length(gpos3A)

mcols(gpos3A)$sample <- Rle("sA")
```

```

sA_counts <- sample(10, npos, replace=TRUE)
mcols(gpos3A)$counts <- sA_counts

mcols(gpos3B)$sample <- Rle("sB")
sB_counts <- sample(10, npos, replace=TRUE)
mcols(gpos3B)$counts <- sB_counts

gpos3 <- c(gpos3A, gpos3B)
gpos3

## Example 4:
library(BSgenome.Scerevisiae.UCSC.sacCer2)
genome <- BSgenome.Scerevisiae.UCSC.sacCer2
gpos4 <- GPos(seqinfo(genome))
gpos4 # all the positions along the genome are represented
mcols(gpos4)$dna <- do.call("c", unname(as.list(genome)))
gpos4

## Note however that, like for any Vector derivative, the length of a
## GPos object cannot exceed '.Machine$integer.max' (i.e. 2^31 on most
## platforms) so the above only works with a "small" genome.
## For example it doesn't work with the Human genome:
library(TxDb.Hsapiens.UCSC.hg19.knownGene)
## Not run:
  GPos(seqinfo(TxDb.Hsapiens.UCSC.hg19.knownGene)) # error!

## End(Not run)

## You can use isSmallGenome() to check upfront whether the genome is
## "small" or not.
isSmallGenome(genome)
isSmallGenome(TxDb.Hsapiens.UCSC.hg19.knownGene)

## -----
## MEMORY USAGE
## -----

## Coercion to GRanges works...
gr4 <- as(gpos4, "GRanges")
gr4
## ... but is generally not a good idea:
object.size(gpos4)
object.size(gr4) # 6951 times bigger than the GPos object!

## Shuffling the order of the positions impacts memory usage:
gpos4r <- rev(gpos4)
object.size(gpos4r) # significantly
gpos4s <- sample(gpos4)
object.size(gpos4s) # even worse!

## AN IMPORTANT NOTE: In the worst situations, GPos still performs as
## good as a GRanges object.
object.size(as(gpos4r, "GRanges")) # same size as 'gpos4r'

```

```

object.size(as(gpos4s, "GRanges")) # same size as 'gpos4s'

## Best case scenario is when the object is strictly sorted (i.e.
## positions are in strict ascending order).
## This can be checked with:
is.unsorted(gpos4, strict=TRUE) # 'gpos4' is strictly sorted

## -----
## USING MEMORY-EFFICIENT METADATA COLUMNS
## -----
## In order to keep memory usage as low as possible, it is recommended
## to use a memory-efficient representation of the metadata columns that
## we want to set on the object. Rle's are particularly well suited for
## this, especially if the metadata columns contain long runs of
## identical values. This is the case for example if we want to use a
## GPos object to represent the coverage of sequencing reads along a
## genome.

## Example 5:
library(pasillaBamSubset)
library(Rsamtools) # for the BamFile() constructor function
bamfile1 <- BamFile(untreated1_chr4())
bamfile2 <- BamFile(untreated3_chr4())
gpos5 <- GPos(seqinfo(bamfile1))
library(GenomicAlignments) # for "coverage" method for BamFile objects
cov1 <- unlist(coverage(bamfile1), use.names=FALSE)
cov2 <- unlist(coverage(bamfile2), use.names=FALSE)
mcols(gpos5) <- DataFrame(cov1, cov2)
gpos5

object.size(gpos5) # lightweight

## Keep only the positions where coverage is at least 10 in one of the
## 2 samples:
gpos5[mcols(gpos5)$cov1 >= 10 | mcols(gpos5)$cov2 >= 10]

## -----
## USING A GPos OBJECT IN A SummarizedExperiment OBJECT
## -----
## Because the GPos class extends the GenomicRanges virtual class, a GPos
## object can be used as the rowRanges component of a SummarizedExperiment
## object.

## As a 1st example, we show how the counts for samples sA and sB in
## 'gpos3' can be stored in a SummarizedExperiment object where the rows
## correspond to unique genomic positions and the columns to samples:
library(SummarizedExperiment)
counts <- cbind(sA=sA_counts, sB=sB_counts)
mcols(gpos3A) <- NULL
rse3 <- SummarizedExperiment(list(counts=counts), rowRanges=gpos3A)
rse3
rowRanges(rse3)
head(assay(rse3))

```

```
## Finally we show how the coverage data from Example 5 can be easily
## stored in a lightweight SummarizedExperiment object:
cov <- mcols(gpos5)
mcols(gpos5) <- NULL
rse5 <- SummarizedExperiment(list(cov=cov), rowRanges=gpos5)
rse5
rowRanges(rse5)
assay(rse5)

## Keep only the positions where coverage is at least 10 in one of the
## 2 samples:
rse5[assay(rse5)$cov1 >= 10 | assay(rse5)$cov2 >= 10]
```

GRanges-class

GRanges objects

Description

The GRanges class is a container for the genomic locations and their associated annotations.

Details

GRanges is a vector of genomic locations and associated annotations. Each element in the vector is comprised of a sequence name, an interval, a [strand](#), and optional metadata columns (e.g. score, GC content, etc.). This information is stored in four components:

`seqnames` a 'factor' [Rle](#) object containing the sequence names.

`ranges` an [IRanges](#) object containing the ranges.

`strand` a 'factor' [Rle](#) object containing the [strand](#) information.

`mcols` a [DataFrame](#) object containing the metadata columns. Columns cannot be named "seqnames", "ranges", "strand", "seqlevels", "seqlengths", "isCircular", "start", "end", "width", or "element".

`seqinfo` a [Seqinfo](#) object containing information about the set of genomic sequences present in the GRanges object.

Constructor

```
GRanges(seqnames=NULL, ranges=NULL, strand=NULL, ..., seqlengths=NULL, seqinfo=NULL)
Creates a GRanges object.
```

`seqnames` NULL, or an [Rle](#) object, character vector, or factor containing the sequence names.

`ranges` NULL, or an [IRanges](#) object containing the ranges.

`strand` NULL, or an [Rle](#) object, character vector, or factor containing the strand information.

... Optional metadata columns. These columns cannot be named "start", "end", "width", or "element".

`seqlengths` NULL, or an integer vector named with `levels(seqnames)` and containing the lengths (or NA) for each level in `levels(seqnames)`.

seqinfo NULL, or a [Seqinfo](#) object containing allowed sequence names, lengths (or NA), and circularity flag, for each level in `levels(seqnames)`.

If `ranges` is not supplied and/or NULL then the constructor proceeds in 2 steps:

1. An initial GRanges object is created with `as(seqnames, "GRanges")`.
2. Then this GRanges object is updated according to whatever non-NULL remaining arguments were passed to the call to `GRanges()`.

As a consequence of this behavior, `GRanges(x)` is equivalent to `as(x, "GRanges")`.

Coercion

In the code snippets below, `x` is a GRanges object.

`as(from, "GRanges")`: Creates a GRanges object from a character vector, a factor, or a RangedData, or RangesList object.

When `from` is a character vector (or a factor), each element in it must represent a genomic range in format `chr1:2501-2800` (unstranded range) or `chr1:2501-2800:+` (stranded range). `..` is also supported as a separator between the start and end positions. Strand can be `+`, `-`, `*`, or missing. The names on `from` are propagated to the returned GRanges object. See `as.character()` and `as.factor()` below for the reverse transformations.

Coercing a data.frame or DataFrame into a GRanges object is also supported. See [makeGRangesFromDataFrame](#) for the details.

`as(from, "RangedData")`: Creates a RangedData object from a GRanges object. The strand and metadata columns become columns in the result. The `seqlengths(from)`, `isCircular(from)`, and `genome(from)` vectors are stored in the metadata columns of `ranges(rd)`.

`as(from, "RangesList")`: Creates a RangesList object from a GRanges object. The strand and metadata columns become *inner* metadata columns (i.e. metadata columns on the ranges). The `seqlengths(from)`, `isCircular(from)`, and `genome(from)` vectors become the metadata columns.

`as.character(x, ignore.strand=FALSE)`: Turn GRanges object `x` into a character vector where each range in `x` is represented by a string in format `chr1:2501-2800:+`. If `ignore.strand` is TRUE or if *all* the ranges in `x` are unstranded (i.e. their strand is set to `*`), then all the strings in the output are in format `chr1:2501-2800`.

The names on `x` are propagated to the returned character vector. Its metadata (`metadata(x)`) and metadata columns (`mcols(x)`) are ignored.

See `as(from, "GRanges")` above for the reverse transformation.

`as.factor(x)`: Equivalent to

```
factor(as.character(x), levels=as.character(sort(unique(x))))
```

See `as(from, "GRanges")` above for the reverse transformation.

Note that `table(x)` is supported on a GRanges object. It is equivalent to, but much faster than, `table(as.factor(x))`.

`as.data.frame(x, row.names = NULL, optional = FALSE, ...)`: Creates a data.frame with columns `seqnames` (factor), `start` (integer), `end` (integer), `width` (integer), `strand` (factor), as well as the additional metadata columns stored in `mcols(x)`. Pass an explicit `stringsAsFactors=TRUE/FALSE` argument via `...` to override the default conversions for the metadata columns in `mcols(x)`.

In the code snippets below, `x` is a [Seqinfo](#) object.

`as(x, "GRanges"), as(x, "GenomicRanges"), as(x, "RangesList")`: Turns [Seqinfo](#) object `x` (with no NA lengths) into a `GRanges` or `RangesList`.

Accessors

In the following code snippets, `x` is a `GRanges` object.

`length(x)`: Get the number of elements.

`seqnames(x), seqnames(x) <- value`: Get or set the sequence names. `value` can be an [Rle](#) object, a character vector, or a factor.

`ranges(x), ranges(x) <- value`: Get or set the ranges. `value` can be a `Ranges` object.

`names(x), names(x) <- value`: Get or set the names of the elements.

`strand(x), strand(x) <- value`: Get or set the strand. `value` can be an `Rle` object, character vector, or factor.

`mcols(x, use.names=FALSE), mcols(x) <- value`: Get or set the metadata columns. If `use.names=TRUE` and the metadata columns are not NULL, then the names of `x` are propagated as the row names of the returned [DataFrame](#) object. When setting the metadata columns, the supplied `value` must be NULL or a data.frame-like object (i.e. [DataTable](#) or `data.frame`) object holding element-wise metadata.

`elementMetadata(x), elementMetadata(x) <- value, values(x), values(x) <- value`: Alternatives to `mcols` functions. Their use is discouraged.

`seqinfo(x), seqinfo(x) <- value`: Get or set the information about the underlying sequences. `value` must be a [Seqinfo](#) object.

`seqlevels(x), seqlevels(x, force=FALSE) <- value`: Get or set the sequence levels. `seqlevels(x)` is equivalent to `seqlevels(seqinfo(x))` or to `levels(seqnames(x))`, those 2 expressions being guaranteed to return identical character vectors on a `GRanges` object. `value` must be a character vector with no NAs. See [?seqlevels](#) for more information.

`seqlengths(x), seqlengths(x) <- value`: Get or set the sequence lengths. `seqlengths(x)` is equivalent to `seqlengths(seqinfo(x))`. `value` can be a named non-negative integer or numeric vector eventually with NAs.

`isCircular(x), isCircular(x) <- value`: Get or set the circularity flags. `isCircular(x)` is equivalent to `isCircular(seqinfo(x))`. `value` must be a named logical vector eventually with NAs.

`genome(x), genome(x) <- value`: Get or set the genome identifier or assembly name for each sequence. `genome(x)` is equivalent to `genome(seqinfo(x))`. `value` must be a named character vector eventually with NAs.

`seqlevelsStyle(x), seqlevelsStyle(x) <- value`: Get or set the seqname style for `x`. See the [seqlevelsStyle](#) generic getter and setter in the **GenomeInfoDb** package for more information.

`score(x), score(x) <- value`: Get or set the “score” column from the element metadata.

`granges(x, use.mcols=FALSE)`: Gets a `GRanges` with only the range information from `x`, unless `use.mcols` is `TRUE`, in which case the metadata columns are also returned. Those columns will include any “extra column slots” if `x` is a specialized `GenomicRanges` derivative.

Ranges methods

In the following code snippets, `x` is a `GRanges` object.

```
start(x), start(x) <- value: Get or set start(ranges(x)).
end(x), end(x) <- value: Get or set end(ranges(x)).
width(x), width(x) <- value: Get or set width(ranges(x)).
```

Splitting and Combining

In the code snippets below, `x` is a `GRanges` object.

```
append(x, values, after = length(x)): Inserts the values into x at the position given by
  after, where x and values are of the same class.
c(x, ...): Combines x and the GRanges objects in ... together. Any object in ... must belong
  to the same class as x, or to one of its subclasses, or must be NULL. The result is an object of
  the same class as x.
c(x, ..., ignore.mcols=FALSE) If the GRanges objects have metadata columns (represented
  as one DataFrame per object), each such DataFrame must have the same columns in order to
  combine successfully. In order to circumvent this restraint, you can pass in an ignore.mcols=TRUE
  argument which will combine all the objects into one and drop all of their metadata columns.
split(x, f, drop=FALSE): Splits x according to f to create a GRangesList object. If f is a list-
  like object then drop is ignored and f is treated as if it was rep(seq_len(length(f)), sapply(f, length)),
  so the returned object has the same shape as f (it also receives the names of f). Otherwise, if
  f is not a list-like object, empty list elements are removed from the returned object if drop is
  TRUE.
```

Subsetting

In the code snippets below, `x` is a `GRanges` object.

```
x[i, j], x[i, j] <- value: Get or set elements i with optional metadata columns mcols(x)[, j],
  where i can be missing; an NA-free logical, numeric, or character vector; or a 'logical' Rle
  object.
x[i, j] <- value: Replaces elements i and optional metadata columns j with value.
head(x, n = 6L): If n is non-negative, returns the first n elements of the GRanges object. If n is
  negative, returns all but the last abs(n) elements of the GRanges object.
rep(x, times, length.out, each): Repeats the values in x through one of the following
  conventions:
  times Vector giving the number of times to repeat each element if of length length(x), or
    to repeat the whole vector if of length 1.
  length.out Non-negative integer. The desired length of the output vector.
  each Non-negative integer. Each element of x is repeated each times.
subset(x, subset): Returns a new object of the same class as x made of the subset using logical
  vector subset, where missing values are taken as FALSE.
tail(x, n = 6L): If n is non-negative, returns the last n elements of the GRanges object. If n is
  negative, returns all but the first abs(n) elements of the GRanges object.
```

`window(x, start = NA, end = NA, width = NA, frequency = NULL, delta = NULL, ...)`:
Extracts the subsequence window from the GRanges object using:

`start, end, width` The start, end, or width of the window. Two of the three are required.

`frequency, delta` Optional arguments that specify the sampling frequency and increment within the window.

In general, this is more efficient than using "[" operator.

`window(x, start = NA, end = NA, width = NA, keepLength = TRUE) <- value`: Replaces the subsequence window specified on the left (i.e. the subsequence in `x` specified by `start`, `end` and `width`) by `value`. `value` must either be of class `class(x)`, belong to a subclass of `class(x)`, be coercible to `class(x)`, or be `NULL`. If `keepLength` is `TRUE`, the elements of `value` are repeated to create a GRanges object with the same number of elements as the width of the subsequence window it is replacing. If `keepLength` is `FALSE`, this replacement method can modify the length of `x`, depending on how the length of the left subsequence window compares to the length of `value`.

`x$name, x$name <- value`: Shortcuts for `mcols(x)$name` and `mcols(x)$name <- value`, respectively. Provided as a convenience, for GRanges objects **only**, and as the result of strong popular demand. Note that those methods are not consistent with the other `$` and `$<-` methods in the IRanges/GenomicRanges infrastructure, and might confuse some users by making them believe that a GRanges object can be manipulated as a data.frame-like object. Therefore we recommend using them only interactively, and we discourage their use in scripts or packages. For the latter, use `mcols(x)$name` and `mcols(x)$name <- value`, instead of `x$name` and `x$name <- value`, respectively.

Note that a GRanges object can be used to as a subscript to subset a list-like object that has names on it. In that case, the names on the list-like object are interpreted as sequence names. In the code snippets below, `x` is a list or [List](#) object with names on it, and the subscript `gr` is a GRanges object with all its seqnames being valid `x` names.

`x[gr]`: Return an object of the same class as `x` and *parallel* to `gr`. More precisely, it's conceptually doing:

```
lapply(gr, function(gr1) x[[seqnames(gr1)]] [ranges(gr1)])
```

Other methods

`show(x)`: By default the `show` method displays 5 head and 5 tail elements. This can be changed by setting the global options `showHeadLines` and `showTailLines`. If the object length is less than (or equal to) the sum of these 2 options plus 1, then the full object is displayed. Note that these options also affect the display of [GAlignments](#) and [GAlignmentPairs](#) objects (defined in the [GenomicAlignments](#) package), as well as other objects defined in the [IRanges](#) and [Biostrings](#) packages (e.g. [IRanges](#) and [DNASTringSet](#) objects).

Examples

```
## -----
## CONSTRUCTION
## -----
## Specifying the bare minimum i.e. seqnames and ranges only. The
## GRanges object will have no names, no strand information, and no
## metadata columns:
gr0 <- GRanges(Rle(c("chr2", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
               IRanges(1:10, width=10:1))
gr0

## Specifying names, strand, metadata columns. They can be set on an
## existing object:
names(gr0) <- head(letters, 10)
strand(gr0) <- Rle(strand(c("-", "+", "*", "+", "-")), c(1, 2, 2, 3, 2))
mcols(gr0)$score <- 1:10
mcols(gr0)$GC <- seq(1, 0, length=10)
gr0

## ... or specified at construction time:
gr <- GRanges(Rle(c("chr2", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
              IRanges(1:10, width=10:1, names=head(letters, 10)),
              Rle(strand(c("-", "+", "*", "+", "-")), c(1, 2, 2, 3, 2)),
```

```

        score=1:10, GC=seq(1, 0, length=10))
stopifnot(identical(gr0, gr))

## Specifying the seqinfo. It can be set on an existing object:
seqinfo <- Seqinfo(paste0("chr", 1:3), c(1000, 2000, 1500), NA, "mock1")
seqinfo(gr0) <- merge(seqinfo(gr0), seqinfo)
seqlevels(gr0) <- seqlevels(seqinfo)

## ... or specified at construction time:
gr <- GRanges(Rle(c("chr2", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
              IRanges(1:10, width=10:1, names=head(letters, 10)),
              Rle(strand(c("-", "+", "*", "+", "-")), c(1, 2, 2, 3, 2)),
              score=1:10, GC=seq(1, 0, length=10),
              seqinfo=seqinfo)
stopifnot(identical(gr0, gr))

## -----
## COERCION
## -----
## From GRanges:
as.character(gr)
as.factor(gr)
as.data.frame(gr)

## From character to GRanges:
x1 <- "chr2:56-125"
as(x1, "GRanges")
as(rep(x1, 4), "GRanges")
x2 <- c(A=x1, B="chr1:25-30:-")
as(x2, "GRanges")

## From data.frame to GRanges:
df <- data.frame(chrom="chr2", start=11:15, end=20:24)
gr3 <- as(df, "GRanges")

## Alternatively, coercion to GRanges can be done by just calling the
## GRanges() constructor on the object to coerce:
gr1 <- GRanges(x1) # same as as(x1, "GRanges")
gr2 <- GRanges(x2) # same as as(x2, "GRanges")
gr3 <- GRanges(df) # same as as(df, "GRanges")

## Sanity checks:
stopifnot(identical(as(x1, "GRanges"), gr1))
stopifnot(identical(as(x2, "GRanges"), gr2))
stopifnot(identical(as(df, "GRanges"), gr3))

## -----
## SUMMARIZING ELEMENTS
## -----
table(seqnames(gr))
table(strand(gr))
sum(width(gr))
table(gr)

```

```

summary(mcols(gr)[,"score"])

## The number of lines displayed in the 'show' method are controlled
## with two global options:
longGR <- sample(gr, 25, replace=TRUE)
longGR

x[gr]

```

GRangesList-class *GRangesList* objects

Description

The GRangesList class is a container for storing a collection of GRanges objects. It is derived from GenomicRangesList.

Constructors

`GRangesList(...)`: Creates a GRangesList object using GRanges objects supplied in ...

`makeGRangesListFromFeatureFragments(seqnames=Rle(factor()), fragmentStarts=list(), fragmentEnds=list(), strand=Rle("")),`
 Constructs a GRangesList object from a list of fragmented features. See the Examples section below.

Accessors

In the following code snippets, `x` is a GRanges object.

`length(x)`: Get the number of list elements.

`names(x), names(x) <- value`: Get or set the names on `x`.

`elementNROWS(x)`: Get a vector of the length of each of the list element.

`isEmpty(x)`: Returns a logical indicating either if the GRangesList has no elements or if all its elements are empty.

`seqnames(x), seqnames(x) <- value`: Get or set the sequence names in the form of an RleList. `value` can be an RleList or CharacterList object.

`ranges(x, use.mcols=FALSE), ranges(x) <- value`: Get or set the ranges in the form of a CompressedIRangesList. `value` can be a RangesList object.

`start(x), start(x) <- value`: Get or set `start(ranges(x))`.

`end(x), end(x) <- value`: Get or set `end(ranges(x))`.

`width(x), width(x) <- value`: Get or set `width(ranges(x))`.

`strand(x), strand(x) <- value`: Get or set the strand in the form of an RleList. `value` can be an RleList, CharacterList or single character. `value` as a single character converts all ranges in `x` to the same value; for selective strand conversion (i.e., mixed "+" and "-") use RleList or CharacterList.

`mcols(x, use.names=FALSE), mcols(x) <- value`: Get or set the metadata columns. `value` can be NULL, or a data.frame-like object (i.e. [DataFrame](#) or `data.frame`) holding element-wise metadata.

`elementMetadata(x), elementMetadata(x) <- value, values(x), values(x) <- value`: Alternatives to `mcols` functions. Their use is discouraged.

`seqinfo(x), seqinfo(x) <- value`: Get or set the information about the underlying sequences. `value` must be a [Seqinfo](#) object.

`seqlevels(x)`, `seqlevels(x, force=FALSE) <- value`: Get or set the sequence levels. `seqlevels(x)` is equivalent to `seqlevels(seqinfo(x))` or to `levels(seqnames(x))`, those 2 expressions being guaranteed to return identical character vectors on a `GRangesList` object. `value` must be a character vector with no NAs. See [?seqlevels](#) for more information.

`seqlengths(x)`, `seqlengths(x) <- value`: Get or set the sequence lengths. `seqlengths(x)` is equivalent to `seqlengths(seqinfo(x))`. `value` can be a named non-negative integer or numeric vector eventually with NAs.

`isCircular(x)`, `isCircular(x) <- value`: Get or set the circularity flags. `isCircular(x)` is equivalent to `isCircular(seqinfo(x))`. `value` must be a named logical vector eventually with NAs.

`genome(x)`, `genome(x) <- value`: Get or set the genome identifier or assembly name for each sequence. `genome(x)` is equivalent to `genome(seqinfo(x))`. `value` must be a named character vector eventually with NAs.

`seqlevelsStyle(x)`, `seqlevelsStyle(x) <- value`: Get or set the seqname style for `x`. See the [seqlevelsStyle](#) generic getter and setter in the **GenomeInfoDb** package for more information.

`score(x)`, `score(x) <- value`: Get or set the “score” metadata column.

Coercion

In the code snippets below, `x` is a `GRangesList` object.

`as.data.frame(x, row.names = NULL, optional = FALSE, ..., value.name = "value", use.outer.mcols)`
Coerces `x` to a data.frame. See `as.data.frame` on the List man page for details ([?List](#)).

`as.list(x, use.names = TRUE)`: Creates a list containing the elements of `x`.

`as(x, "IRangesList")`: Turns `x` into an [IRangesList](#) object.

`as(from, "GRangesList")`: Creates a `GRangesList` object from a [RangedDataList](#) object.

Subsetting

In the following code snippets, `x` is a `GRangesList` object.

`x[i, j]`, `x[i, j] <- value`: Get or set elements `i` with optional metadata columns `mcols(x)[, j]`, where `i` can be missing; an NA-free logical, numeric, or character vector; a 'logical' Rle object, or an `AtomicList` object.

`x[[i]]`, `x[[i]] <- value`: Get or set element `i`, where `i` is a numeric or character vector of length 1.

`x$name`, `x$name <- value`: Get or set element name, where `name` is a name or character vector of length 1.

`head(x, n = 6L)`: If `n` is non-negative, returns the first `n` elements of the `GRangesList` object. If `n` is negative, returns all but the last `abs(n)` elements of the `GRangesList` object.

`rep(x, times, length.out, each)`: Repeats the values in `x` through one of the following conventions:

`times` Vector giving the number of times to repeat each element if of length `length(x)`, or to repeat the whole vector if of length 1.

`length.out` Non-negative integer. The desired length of the output vector.

each Non-negative integer. Each element of `x` is repeated each times.

`subset(x, subset)`: Returns a new object of the same class as `x` made of the subset using logical vector `subset`, where missing values are taken as `FALSE`.

`tail(x, n = 6L)`: If `n` is non-negative, returns the last `n` elements of the `GRanges` object. If `n` is negative, returns all but the first `abs(n)` elements of the `GRanges` object.

Combining

In the code snippets below, `x` is a `GRangesList` object.

`c(x, ...)`: Combines `x` and the `GRangesList` objects in `...` together. Any object in `...` must belong to the same class as `x`, or to one of its subclasses, or must be `NULL`. The result is an object of the same class as `x`.

`append(x, values, after = length(x))`: Inserts the values into `x` at the position given by `after`, where `x` and `values` are of the same class.

`unlist(x, recursive = TRUE, use.names = TRUE)`: Concatenates the elements of `x` into a single `GRanges` object.

Looping

In the code snippets below, `x` is a `GRangesList` object.

`endoapply(X, FUN, ...)`: Similar to `lapply`, but performs an endomorphism, i.e. returns an object of `class(X)`.

`lapply(X, FUN, ...)`: Like the standard `lapply` function defined in the base package, the `lapply` method for `GRangesList` objects returns a list of the same length as `X`, with each element being the result of applying `FUN` to the corresponding element of `X`.

`Map(f, ...)`: Applies a function to the corresponding elements of given `GRangesList` objects.

`mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE)`: Like the standard `mapply` function defined in the base package, the `mapply` method for `GRangesList` objects is a multivariate version of `sapply`.

`mendoapply(FUN, ..., MoreArgs = NULL)`: Similar to `mapply`, but performs an endomorphism across multiple objects, i.e. returns an object of `class(list(...)[[1]])`.

`Reduce(f, x, init, right = FALSE, accumulate = FALSE)`: Uses a binary function to successively combine the elements of `x` and a possibly given initial value.

f A binary argument function.

init An R object of the same kind as the elements of `x`.

right A logical indicating whether to proceed from left to right (default) or from right to left.

nomatch The value to be returned in the case when "no match" (no element satisfying the predicate) is found.

`sapply(X, FUN, ..., simplify=TRUE, USE.NAMES=TRUE)`: Like the standard `sapply` function defined in the base package, the `sapply` method for `GRangesList` objects is a user-friendly version of `lapply` by default returning a vector or matrix if appropriate.

inter-range-methods *Inter range transformations of a GRanges or GRangesList object*

Description

This man page documents *inter range transformations* of a [GenomicRanges](#) object (i.e. of an object that belongs to the [GenomicRanges](#) class or one of its subclasses, this includes for example [GRanges](#) objects), or a [GRangesList](#) object.

See `?`intra-range-methods`` and `?`inter-range-methods`` in the [IRanges](#) package for a quick introduction to *intra range* and *inter range transformations*.

See `?`intra-range-methods`` for *intra range transformations* of a [GenomicRanges](#) object or [GRangesList](#) object.

Usage

```
## S4 method for signature 'GenomicRanges'
range(x, ..., ignore.strand=FALSE, na.rm=FALSE)
## S4 method for signature 'GRangesList'
range(x, ..., ignore.strand=FALSE, na.rm=FALSE)

## S4 method for signature 'GenomicRanges'
reduce(x, drop.empty.ranges=FALSE, min.gapwidth=1L, with.revmap=FALSE,
       with.inframe.attrib=FALSE, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
reduce(x, drop.empty.ranges=FALSE, min.gapwidth=1L,
       with.inframe.attrib=FALSE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
gaps(x, start=1L, end=seqlengths(x))

## S4 method for signature 'GenomicRanges'
disjoin(x, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
disjoin(x, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
isDisjoint(x, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
isDisjoint(x, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
disjointBins(x, ignore.strand=FALSE)
```

Arguments

<code>x</code>	A GenomicRanges object.
<code>drop.empty.ranges</code> , <code>min.gapwidth</code> , <code>with.revmap</code> , <code>with.inframe.attrib</code> , <code>start</code> , <code>end</code>	See <code>?`inter-range-methods`</code> in the IRanges package.
<code>ignore.strand</code>	TRUE or FALSE. Whether the strand of the input ranges should be ignored or not. See details below.
<code>...</code>	For range, additional GenomicRanges objects to consider. Ignored otherwise.
<code>na.rm</code>	Ignored.

Details

On a [GRanges](#) object: `range` returns an object of the same type as `x` containing range bounds for each distinct (seqname, strand) pairing. The names (`names(x)`) and the metadata columns in `x` are dropped.

`reduce` returns an object of the same type as `x` containing reduced ranges for each distinct (seqname, strand) pairing. The names (`names(x)`) and the metadata columns in `x` are dropped. See [?reduce](#) for more information about range reduction and for a description of the optional arguments.

`gaps` returns an object of the same type as `x` containing complemented ranges for each distinct (seqname, strand) pairing. The names (`names(x)`) and the columns in `x` are dropped. For the start and end arguments of this `gaps` method, it is expected that the user will supply a named integer vector (where the names correspond to the appropriate seqlevels). See [?gaps](#) for more information about range complements and for a description of the optional arguments.

`disjoin` returns an object of the same type as `x` containing disjoint ranges for each distinct (seqname, strand) pairing. The names (`names(x)`) and the metadata columns in `x` are dropped.

`isDisjoint` returns a logical value indicating whether the ranges in `x` are disjoint (i.e. non-overlapping).

`disjointBins` returns bin indexes for the ranges in `x`, such that ranges in the same bin do not overlap. If `ignore.strand=FALSE`, the two features cannot overlap if they are on different strands.

On a [GRangesList](#) object: When they are supported on [GRangesList](#) object `x`, the above inter range transformations will apply the transformation to each of the list elements in `x` and return a list-like object *parallel* to `x` (i.e. with 1 list element per list element in `x`). If `x` has names on it, they're propagated to the returned object.

Description

This man page documents *intra range transformations* of a [GenomicRanges](#) object (i.e. of an object that belongs to the [GenomicRanges](#) class or one of its subclasses, this includes for example [GRanges](#) objects), or a [GRangesList](#) object.

See `?`intra-range-methods`` and `?`inter-range-methods`` in the [IRanges](#) package for a quick introduction to *intra range* and *inter range transformations*.

Intra range methods for [GAlignments](#) and [GAlignmentsList](#) objects are defined and documented in the [GenomicAlignments](#) package.

See `?`inter-range-methods`` for *inter range transformations* of a [GenomicRanges](#) or [GRangesList](#) object.

Usage

```
## S4 method for signature 'GenomicRanges'
shift(x, shift=0L, use.names=TRUE)
## S4 method for signature 'GRangesList'
shift(x, shift=0L, use.names=TRUE)

## S4 method for signature 'GenomicRanges'
narrow(x, start=NA, end=NA, width=NA, use.names=TRUE)

## S4 method for signature 'GenomicRanges'
resize(x, width, fix="start", use.names=TRUE,
        ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
resize(x, width, fix="start", use.names=TRUE,
        ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
flank(x, width, start=TRUE, both=FALSE,
       use.names=TRUE, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
flank(x, width, start=TRUE, both=FALSE,
       use.names=TRUE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
promoters(x, upstream=2000, downstream=200, ...)
## S4 method for signature 'GRangesList'
promoters(x, upstream=2000, downstream=200, ...)

## S4 method for signature 'GenomicRanges'
restrict(x, start=NA, end=NA, keep.all.ranges=FALSE,
         use.names=TRUE)
## S4 method for signature 'GRangesList'
restrict(x, start=NA, end=NA, keep.all.ranges=FALSE,
         use.names=TRUE)
```

```
## S4 method for signature 'GenomicRanges'
trim(x, use.names=TRUE)
```

Arguments

`x` A [GenomicRanges](#) or [GRangesList](#) object.

`shift`, `use.names`, `start`, `end`, `width`, `both`, `fix`, `keep.all.ranges`, `upstream`, `downstream`
See ?`intra-range-methods`.

`ignore.strand` TRUE or FALSE. Whether the strand of the input ranges should be ignored or not.
See details below.

... Additional arguments to methods.

Details

- `shift` behaves like the `shift` method for [Ranges](#) objects. See ?`intra-range-methods` for the details.
- `()narrow` on a [GenomicRanges](#) object behaves like on a [Ranges](#) object. See ?`intra-range-methods` for the details.
A major difference though is that it returns a [GenomicRanges](#) object instead of a [Ranges](#) object. The returned object is *parallel* (i.e. same length and names) to the original object `x`.
- `resize` returns an object of the same type and length as `x` containing intervals that have been resized to width `width` based on the `strand(x)` values. Elements where `strand(x) == "+"` or `strand(x) == "*"` are anchored at `start(x)` and elements where `strand(x) == "-"` are anchored at the `end(x)`. The `use.names` argument determines whether or not to keep the names on the ranges.
- `flank` returns an object of the same type and length as `x` containing intervals of width `width` that flank the intervals in `x`. The `start` argument takes a logical indicating whether `x` should be flanked at the "start" (TRUE) or the "end" (FALSE), which for `strand(x) != "-"` is `start(x)` and `end(x)` respectively and for `strand(x) == "-"` is `end(x)` and `start(x)` respectively. The `both` argument takes a single logical value indicating whether the flanking region width positions extends *into* the range. If `both=TRUE`, the resulting range thus straddles the end point, with `width` positions on either side.
- `promoters` returns an object of the same type and length as `x` containing promoter ranges. Promoter ranges extend around the transcription start site (TSS) which is defined as `start(x)`. The `upstream` and `downstream` arguments define the number of nucleotides in the 5' and 3' direction, respectively. The full range is defined as,
(`start(x) - upstream`) to (`start(x) + downstream - 1`).
Ranges on the `*` strand are treated the same as those on the `+` strand. When no `seqlengths` are present in `x`, it is possible to have non-positive start values in the promoter ranges. This occurs when $(TSS - upstream) < 1$. In the equal but opposite case, the end values of the ranges may extend beyond the chromosome end when $(TSS + downstream + 1) > \text{'chromosome end'}$. When `seqlengths` are not NA the promoter ranges are kept within the bounds of the defined `seqlengths`.
- `restrict` returns an object of the same type and length as `x` containing restricted ranges for distinct `seqnames`. The `start` and `end` arguments can be a named numeric vector of `seqnames` for the ranges to be restricted or a numeric vector of length 1 if the restriction operation is to be

applied to all the sequences in `x`. See `?`intra-range-methods`` for more information about range restriction and for a description of the optional arguments.

- `trim` trims out-of-bound ranges located on non-circular sequences whose length is not NA.

```

```
restrict(grl, start=3)
```

```
makeGRangesFromDataFrame
```

Make a GRanges object from a data.frame or DataFrame

Description

makeGRangesFromDataFrame takes a data-frame-like object as input and tries to automatically find the columns that describe genomic ranges. It returns them as a [GRanges](#) object.

makeGRangesFromDataFrame is also the workhorse behind the coercion method from data.frame (or [DataFrame](#)) to [GRanges](#).

Usage

```
makeGRangesFromDataFrame(df,
  keep.extra.columns=FALSE,
  ignore.strand=FALSE,
  seqinfo=NULL,
  seqnames.field=c("seqnames", "seqname",
                  "chromosome", "chrom",
                  "chr", "chromosome_name",
                  "seqid"),
  start.field="start",
  end.field=c("end", "stop"),
  strand.field="strand",
  starts.in.df.are.0based=FALSE)
```

Arguments

df	A data.frame or DataFrame object. If not, then the function tries to turn df into a data frame with <code>as.data.frame(df)</code> .
keep.extra.columns	TRUE or FALSE (the default). If TRUE, the columns in df that are not used to form the genomic ranges of the returned GRanges object are then returned as metadata columns on the object. Otherwise, they are ignored. If df has a width column, then it's always ignored.
ignore.strand	TRUE or FALSE (the default). If TRUE, then the strand of the returned GRanges object is set to "*".
seqinfo	Either NULL, or a Seqinfo object, or a character vector of seqlevels, or a named numeric vector of sequence lengths. When not NULL, it must be compatible with the genomic ranges in df i.e. it must include at least the sequence levels represented in df.
seqnames.field	A character vector of recognized names for the column in df that contains the chromosome name (a.k.a. sequence name) associated with each genomic range. Only the first name in seqnames.field that is found in <code>colnames(df)</code> is used. If no one is found, then an error is raised.

<code>start.field</code>	A character vector of recognized names for the column in <code>df</code> that contains the start positions of the genomic ranges. Only the first name in <code>start.field</code> that is found in <code>colnames(df)</code> is used. If no one is found, then an error is raised.
<code>end.field</code>	A character vector of recognized names for the column in <code>df</code> that contains the end positions of the genomic ranges. Only the first name in <code>start.field</code> that is found in <code>colnames(df)</code> is used. If no one is found, then an error is raised.
<code>strand.field</code>	A character vector of recognized names for the column in <code>df</code> that contains the strand associated with each genomic range. Only the first name in <code>strand.field</code> that is found in <code>colnames(df)</code> is used. If no one is found or if <code>ignore.strand</code> is <code>TRUE</code> , then the strand of the returned <code>GRanges</code> object is set to <code>"*"</code> .
<code>starts.in.df.are.0based</code>	<code>TRUE</code> or <code>FALSE</code> (the default). If <code>TRUE</code> , then the start positions of the genomic ranges in <code>df</code> are considered to be <i>0-based</i> and are converted to <i>1-based</i> in the returned <code>GRanges</code> object. This feature is intended to make it more convenient to handle input that contains data obtained from resources using the "0-based start" convention. A notorious example of such resource is the UCSC Table Browser (http://genome.ucsc.edu/cgi-bin/hgTables).

Value

A `GRanges` object with one element per row in the input.

If the `seqinfo` argument was supplied, the returned object will have exactly the `seqlevels` specified in `seqinfo` and in the same order. Otherwise, the `seqlevels` are ordered according to the output of the `rankSeqlevels` function (except if `df` contains the `seqnames` in the form of a factor-Rle, in which case the levels of the factor-Rle become the `seqlevels` of the returned object and with no re-ordering).

If `df` has non-automatic row names (i.e. `rownames(df)` is not `NULL` and is not `seq_len(nrow(df))`), then they will be used to set names on the returned `GRanges` object.

Note

Coercing `data.frame` or `DataFrame` `df` into a `GRanges` object (with `as(df, "GRanges")`), or calling `GRanges(df)`, are both equivalent to calling `makeGRangesFromDataFrame(df, keep.extra.columns=TRUE)`.

Author(s)

H. Pagès, based on a proposal by Kasper Daniel Hansen

Examples

```

## -----
## BASIC EXAMPLES
## -----

df <- data.frame(chr="chr1", start=11:15, end=12:16,
                 strand=c("+","-","+","*","."), score=1:5)
df
makeGRangesFromDataFrame(df) # strand value "." is replaced with "*"

## The strand column is optional:
df <- data.frame(chr="chr1", start=11:15, end=12:16, score=1:5)
makeGRangesFromDataFrame(df)

gr <- makeGRangesFromDataFrame(df, keep.extra.columns=TRUE)
gr2 <- as(df, "GRanges") # equivalent to the above
stopifnot(identical(gr, gr2))
gr2 <- GRanges(df) # equivalent to the above
stopifnot(identical(gr, gr2))

makeGRangesFromDataFrame(df, ignore.strand=TRUE)
makeGRangesFromDataFrame(df, keep.extra.columns=TRUE,
                         ignore.strand=TRUE)

makeGRangesFromDataFrame(df, seqinfo=paste0("chr", 4:1))
makeGRangesFromDataFrame(df, seqinfo=c(chrM=NA, chr1=500, chrX=100))
makeGRangesFromDataFrame(df, seqinfo=Seqinfo(paste0("chr", 4:1)))

## -----
## ABOUT AUTOMATIC DETECTION OF THE seqnames/start/end/strand COLUMNS
## -----

## Automatic detection of the seqnames/start/end/strand columns is
## case insensitive:
df <- data.frame(ChRoM="chr1", StarT=11:15, stoP=12:16,
                 STRAND=c("+","-","+","*","."), score=1:5)
makeGRangesFromDataFrame(df)

## It also ignores a common prefix between the start and end columns:
df <- data.frame(seqnames="chr1", tx_start=11:15, tx_end=12:16,
                 strand=c("+","-","+","*","."), score=1:5)
makeGRangesFromDataFrame(df)

## The common prefix between the start and end columns is used to
## disambiguate between more than one seqnames column:
df <- data.frame(chrom="chr1", tx_start=11:15, tx_end=12:16,
                 tx_chr="chr2", score=1:5)
makeGRangesFromDataFrame(df)

## -----
## 0-BASED VS 1-BASED START POSITIONS
## -----

```

```

if (require(rtracklayer)) {
  session <- browserSession()
  genome(session) <- "sacCer2"
  query <- ucscTableQuery(session, "Most Conserved")
  df <- getTable(query)

  ## A common pitfall is to forget that the UCSC Table Browser uses the
  ## "0-based start" convention:
  gr0 <- makeGRangesFromDataFrame(df, keep.extra.columns=TRUE)
  head(gr0)
  min(start(gr0))

  ## The start positions need to be converted into 1-based positions,
  ## to adhere to the convention used in Bioconductor:
  gr1 <- makeGRangesFromDataFrame(df, keep.extra.columns=TRUE,
                                  starts.in.df.are.0based=TRUE)
  head(gr1)
}

```

nearest-methods

Finding the nearest genomic range neighbor

Description

The nearest, precede, follow, distance and distanceToNearest methods for [GenomicRanges](#) objects and subclasses.

Usage

```

## S4 method for signature 'GenomicRanges,GenomicRanges'
precede(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)
## S4 method for signature 'GenomicRanges,missing'
precede(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
follow(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)
## S4 method for signature 'GenomicRanges,missing'
follow(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
nearest(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)
## S4 method for signature 'GenomicRanges,missing'
nearest(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
distanceToNearest(x, subject, ignore.strand=FALSE, ...)
## S4 method for signature 'GenomicRanges,missing'

```

```
distanceToNearest(x, subject, ignore.strand=FALSE, ...)

## S4 method for signature 'GenomicRanges,GenomicRanges'
distance(x, y, ignore.strand=FALSE, ...)
```

Arguments

x	The query GenomicRanges instance.
subject	The subject GenomicRanges instance within which the nearest neighbors are found. Can be missing, in which case x is also the subject.
y	For the distance method, a GRanges instance. Cannot be missing. If x and y are not the same length, the shortest will be recycled to match the length of the longest.
select	Logic for handling ties. By default, all methods select a single interval (arbitrary for nearest, the first by order in subject for precede, and the last for follow). When select="all" a Hits object is returned with all matches for x. If x does not have a match in subject the x is not included in the Hits object.
ignore.strand	A logical indicating if the strand of the input ranges should be ignored. When TRUE, strand is set to '+'.
...	Additional arguments for methods.

Details

- nearest: Performs conventional nearest neighbor finding. Returns an integer vector containing the index of the nearest neighbor range in subject for each range in x. If there is no nearest neighbor NA is returned. For details of the algorithm see the man page in [IRanges](#), ?nearest.
- precede: For each range in x, precede returns the index of the range in subject that is directly preceded by the range in x. Overlapping ranges are excluded. NA is returned when there are no qualifying ranges in subject.
- follow: The opposite of precede, follow returns the index of the range in subject that is directly followed by the range in x. Overlapping ranges are excluded. NA is returned when there are no qualifying ranges in subject.
- Orientation and Strand: The relevant orientation for precede and follow is 5' to 3', consistent with the direction of translation. Because positional numbering along a chromosome is from left to right and transcription takes place from 5' to 3', precede and follow can appear to have 'opposite' behavior on the + and - strand. Using positions 5 and 6 as an example, 5 precedes 6 on the + strand but follows 6 on the - strand.

A range with strand * can be compared to ranges on either the + or - strand. Below we outline the priority when ranges on multiple strands are compared. When ignore.strand=TRUE all ranges are treated as if on the + strand.

- x on + strand can match to ranges on both + and * strands. In the case of a tie the first range by order is chosen.
- x on - strand can match to ranges on both - and * strands. In the case of a tie the first range by order is chosen.
- x on * strand can match to ranges on any of +, - or * strands. In the case of a tie the first range by order is chosen.

- `distanceToNearest`: Returns the distance for each range in `x` to its nearest neighbor in the subject.
- `distance`: Returns the distance for each range in `x` to the range in `y`. The behavior of `distance` has changed in Bioconductor 2.12. See the man page `?distance` in `IRanges` for details.

Value

For `nearest`, `precede` and `follow`, an integer vector of indices in `subject`, or a [Hits](#) if `select="all"`.

For `distanceToNearest`, a [Hits](#) object with a column for the query index (`queryHits`), subject index (`subjectHits`) and the distance between the pair.

For `distance`, an integer vector of distances between the ranges in `x` and `y`.

Examples

```
## -----
## precede() and follow()
## -----
query <- GRanges("A", IRanges(c(5, 20), width=1), strand="+")
subject <- GRanges("A", IRanges(rep(c(10, 15), 2), width=1),
                    strand=c("+", "+", "-", "-"))

precede(query, subject)
follow(query, subject)

strand(query) <- "-"
precede(query, subject)
follow(query, subject)

## ties choose first in order
query <- GRanges("A", IRanges(10, width=1), c("+", "-", "*"))
subject <- GRanges("A", IRanges(c(5, 5, 5, 15, 15), width=1),
                    rep(c("+", "-", "*"), 2))

precede(query, subject)
precede(query, rev(subject))

## ignore.strand=TRUE treats all ranges as '+'
precede(query[1], subject[4:6], select="all", ignore.strand=FALSE)
```

```

precede(query[1], subject[4:6], select="all", ignore.strand=TRUE)

## -----
## nearest()
## -----
## When multiple ranges overlap an "arbitrary" range is chosen
query <- GRanges("A", IRanges(5, 15))
subject <- GRanges("A", IRanges(c(1, 15), c(5, 19)))
nearest(query, subject)

## select="all" returns all hits
nearest(query, subject, select="all")

## Ranges in 'x' will self-select when 'subject' is present
query <- GRanges("A", IRanges(c(1, 10), width=5))
nearest(query, query)

## Ranges in 'x' will not self-select when 'subject' is missing
nearest(query)

## -----
## distance(), distanceToNearest()
## -----
## Adjacent, overlap, separated by 1
query <- GRanges("A", IRanges(c(1, 2, 10), c(5, 8, 11)))
subject <- GRanges("A", IRanges(c(6, 5, 13), c(10, 10, 15)))
distance(query, subject)

## recycling
distance(query[1], subject)

## zero-width ranges
zw <- GRanges("A", IRanges(4,3))
stopifnot(distance(zw, GRanges("A", IRanges(3,4))) == 0L)
sapply(-3:3, function(i)
  distance(shift(zw, i), GRanges("A", IRanges(4,3))))

query <- GRanges(c("A", "B"), IRanges(c(1, 5), width=1))
distanceToNearest(query, subject)

## distance() with GRanges and TxDb see the
## '?'distance,GenomicRanges,TxDb-method' man
## page in the GenomicFeatures package.

```

phicoef

Calculate the "phi coefficient" between two binary variables

Description

The phicoef function calculates the "phi coefficient" between two binary variables.

Usage

```
phicoef(x, y=NULL)
```

Arguments

`x`, `y` Two logical vectors of the same length. If `y` is not supplied, `x` must be a 2x2 integer matrix (or an integer vector of length 4) representing the contingency table of two binary variables.

Value

The "phi coefficient" between the two binary variables. This is a single numeric value ranging from -1 to +1.

Author(s)

H. Pagès

References

http://en.wikipedia.org/wiki/Phi_coefficient

Examples

```
set.seed(33)
x <- sample(c(TRUE, FALSE), 100, replace=TRUE)
y <- sample(c(TRUE, FALSE), 100, replace=TRUE)
phicoef(x, y)
phicoef(rep(x, 10), c(rep(x, 9), y))

stopifnot(phicoef(table(x, y)) == phicoef(x, y))
stopifnot(phicoef(y, x) == phicoef(x, y))
stopifnot(phicoef(x, !y) == - phicoef(x, y))
stopifnot(phicoef(x, x) == 1)
```

range-squeezers

Squeeze the ranges out of a range-based object

Description

S4 generic functions for squeezing the ranges out of a range-based object. `granges` returns them in a [GRanges](#) object, `grglist` in a [GRangesList](#) object, and `rglist` in a [RangesList](#) object.

Usage

```
granges(x, use.names=TRUE, use.mcols=FALSE, ...)
grglist(x, use.names=TRUE, use.mcols=FALSE, ...)
rglist(x, use.names=TRUE, use.mcols=FALSE, ...)
```

Arguments

<code>x</code>	A range-based object e.g. a RangedSummarizedExperiment , GAlignments , GAlignmentPairs , GAlignmentsList or a Pairs object containing ranges.
<code>use.names</code>	TRUE (the default) or FALSE. Whether or not the names on <code>x</code> (accessible with <code>names(x)</code>) should be propagated to the returned object.
<code>use.mcols</code>	TRUE or FALSE (the default). Whether or not the metadata columns on <code>x</code> (accessible with <code>mcols(x)</code>) should be propagated to the returned object.
<code>...</code>	Additional arguments, for use in specific methods.

Details

The **GenomicRanges**, **SummarizedExperiment**, and **GenomicAlignments** packages define and document methods for various types of range-based objects (e.g. for [RangedSummarizedExperiment](#), [GAlignments](#), [GAlignmentPairs](#), and [GAlignmentsList](#) objects). Other Bioconductor packages might as well.

Note that these functions can be seen as a specific kind of *object getters* as well as functions performing coercion.

For some objects (e.g. [GAlignments](#) and [GAlignmentPairs](#) objects defined in the **GenomicAlignments** package), `as(x, "GRanges")`, `as(x, "GRangesList")`, and `as(x, "RangesList")`, are equivalent to `granges(x, use.names=TRUE, use.mcols=TRUE)`, `grglist(x, use.names=TRUE, use.mcols=TRUE)`, and `rglist(x, use.names=TRUE, use.mcols=TRUE)`, respectively.

Value

A [GRanges](#) object for `granges`.

A [GRangesList](#) object for `grglist`.

A [RangesList](#) object for `rglist`.

If `x` is a vector-like object (e.g. [GAlignments](#)), the returned object is expected to be *parallel* to `x`, that is, the *i*-th element in the output corresponds to the *i*-th element in the input.

If `use.names` is TRUE, then the names on `x` (if any) are propagated to the returned object. If `use.mcols` is TRUE, then the metadata columns on `x` (if any) are propagated to the returned object.

Author(s)

H. Pagès

- [RangesList](#) objects in the **IRanges** package.
- [RangedSummarizedExperiment](#) objects in the **SummarizedExperiment** packages.
- [GAlignments](#), [GAlignmentPairs](#), and [GAlignmentsList](#) objects in the **GenomicAlignments** package.

Examples

```
## See ?GAlignments in the GenomicAlignments package for some
## examples.
```

```
setops-methods      Set operations on genomic ranges
```

Description

Performs set operations on [GRanges](#) and [GRangesList](#) objects.

NOTE: The [punion](#), [pintersect](#), [psetdiff](#), and [pgap](#) generic functions and methods for [Ranges](#) objects are defined and documented in the **IRanges** package.

Usage

```
## Vector-wise set operations
## -----

## S4 method for signature 'GenomicRanges,GenomicRanges'
union(x, y, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
intersect(x, y, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
setdiff(x, y, ignore.strand=FALSE)

## Element-wise (aka "parallel") set operations
## -----

## S4 method for signature 'GRanges,GRanges'
punion(x, y, fill.gap=FALSE, ignore.strand=FALSE)

## S4 method for signature 'GRanges,GRanges'
pintersect(x, y, drop.nohit.ranges=FALSE,
           ignore.strand=FALSE, strict.strand=FALSE)

## S4 method for signature 'GRanges,GRanges'
psetdiff(x, y, ignore.strand=FALSE)
```

Arguments

`x`, `y` For `union`, `intersect`, and `setdiff`: 2 [GenomicRanges](#) objects or 2 [GRangesList](#) objects.
For `punion` and `pintersect`: 2 [GRanges](#) objects, or 1 [GRanges](#) object and 1 [GRangesList](#) object.

	For <code>psetdiff</code> : <code>x</code> must be a <code>GRanges</code> object and <code>y</code> can be a <code>GRanges</code> or <code>GRangesList</code> object.
	For <code>pgap</code> : 2 <code>GRanges</code> objects.
	In addition, for the <i>parallel</i> operations, <code>x</code> and <code>y</code> must be of equal length (i.e. <code>length(x) == length(y)</code>).
<code>fill.gap</code>	Logical indicating whether or not to force a union by using the rule <code>start = min(start(x), start(y))</code> .
<code>ignore.strand</code>	For set operations: If set to <code>TRUE</code> , then the strand of <code>x</code> and <code>y</code> is set to "*" prior to any computation. For parallel set operations: If set to <code>TRUE</code> , the strand information is ignored in the computation and the result has the strand information of <code>x</code> .
<code>drop.nohit.ranges</code>	If <code>TRUE</code> then elements in <code>x</code> that don't intersect with their corresponding element in <code>y</code> are removed from the result (so the returned object is no more parallel to the input). If <code>FALSE</code> (the default) then nothing is removed and a <code>hit</code> metadata column is added to the returned object to indicate elements in <code>x</code> that intersect with the corresponding element in <code>y</code> . For those that don't, the reported intersection is a zero-width range that has the same start as <code>x</code> .
<code>strict.strand</code>	If set to <code>FALSE</code> (the default), features on the "*" strand are treated as occurring on both the "+" and "-" strand. If set to <code>TRUE</code> , the strand of intersecting elements must be strictly the same.

Details

The `pintersect` methods involving `GRanges` and/or `GRangesList` objects use the triplet (sequence name, range, strand) to determine the element by element intersection of features, where a strand value of "*" is treated as occurring on both the "+" and "-" strand (unless `strict.strand` is set to `TRUE`, in which case the strand of intersecting elements must be strictly the same).

The `psetdiff` methods involving `GRanges` and/or `GRangesList` objects use the triplet (sequence name, range, strand) to determine the element by element set difference of features, where a strand value of "*" is treated as occurring on both the "+" and "-" strand.

Value

For `union`, `intersect`, and `setdiff`: a `GRanges` object if `x` and `y` are `GenomicRanges` objects, and a `GRangesList` object if they are `GRangesList` objects.

For `punion` and `pintersect`: when `x` or `y` is not a `GRanges` object, an object of the same class as this non-`GRanges` object. Otherwise, a `GRanges` object.

For `psetdiff`: either a `GRanges` object when both `x` and `y` are `GRanges` objects, or a `GRangesList` object when `y` is a `GRangesList` object.

For `pgap`: a `GRanges` object.

## S4 method for signature 'logical'
invertStrand(x)
## S4 method for signature 'Rle'
invertStrand(x)
## S4 method for signature 'RleList'
invertStrand(x)

```

Arguments

x	The object from which to obtain a <i>strand factor</i> , <i>strand factor Rle</i> , or <i>strand factor RleList</i> object. Can be missing. See Details and Value sections below for more information.
value	Replacement value for the strand.

Details

All the strand and invertStrand methods documented here return either a *strand factor*, *strand factor Rle*, or *strand factor RleList* object. These are factor, factor-*Rle*, or factor-*RleList* objects containing the "standard strand levels" (i.e. +, -, and *) and no NAs.

Value

All the strand and invertStrand methods documented here return an object that is *parallel* to input object *x* when *x* is a character, factor, integer, logical, [Rle](#), or [RleList](#) object.

For the strand methods:

- If *x* is missing, returns an empty factor with the "standard strand levels" i.e. +, -, and *.
- If *x* is a character vector or factor, it is coerced to a factor with the levels listed above. NA values in *x* are not accepted.
- If *x* is an integer vector, it is coerced to a factor with the levels listed above. 1, -1, and NA values in *x* are mapped to the +, -, and * levels respectively.
- If *x* is a logical vector, it is coerced to a factor with the levels listed above. FALSE, TRUE, and NA values in *x* are mapped to the +, -, and * levels respectively.
- If *x* is a character-, factor-, integer-, or logical-[Rle](#), it is transformed with `runValue(x) <- strand(runValue(x))` and returned.
- If *x* is an [RleList](#) object, each list element in *x* is transformed by calling `strand()` on it and the resulting [RleList](#) object is returned. More precisely the returned object is `endoapply(x, strand)`. Note that in addition to being *parallel* to *x*, this object also has the same *shape* as *x* (i.e. its list elements have the same lengths as in *x*).
- If *x* inherits from `DataTable`, the "strand" column is passed thru `strand()` and returned. If *x* has no "strand" column, this return value is populated with *s.

Each `invertStrand` method returns the same object as its corresponding `strand` method but with "+" and "-" switched.

tile-methods

Tile a GenomicRanges object

Description

tile method for **GenomicRanges**. Partitions each range into a set of tiles. Tiles are defined in terms of their number or width.

Usage

```

## S4 method for signature 'GenomicRanges'
tile(x, n, width)

```

Arguments

x	A GenomicRanges object, like a GRanges .
n	The number of tiles to generate. See ?tile in the IRanges package for more information about this argument.
width	The (maximum) width of each tile. See ?tile in the IRanges package for more information about this argument.

Details

Splits `x` into a `GRangesList`, each element of which corresponds to a tile, or partition, of `x`. Specify the tile geometry with either `n` or `width` (not both). Passing `n` creates `n` tiles of approximately equal width, truncated by sequence end, while passing `width` tiles the region with ranges of the given width, again truncated by sequence end.

Value

A `GRangesList` object, each element of which corresponds to a tile.

Author(s)

M. Lawrence

See Also

[tile](#) in the **IRanges** package.

Examples

```
gr <- GRanges(
  seqnames=Rle(c("chr1", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
  ranges=IRanges(1:10, end=11),
  strand=Rle(strand(c("-", "+", "*"), "+", "-")), c(1, 2, 2, 3, 2)),
  seqlengths=c(chr1=11, chr2=12, chr3=13))

# split every range in half
tiles <- tile(gr, n = 2L)
stopifnot(all(elementNROWS(tiles) == 2L))

# split ranges into subranges of width 2
# odd width ranges must contain one subrange of width 1
tiles <- tile(gr, width = 2L)
stopifnot(all(all(width(tiles) %in% c(1L, 2L))))
```

tileGenome

Put (virtual) tiles on a given genome

Description

`tileGenome` returns a set of genomic regions that form a partitioning of the specified genome. Each region is called a "tile".

Usage

```
tileGenome(seqlengths, ntile, tilewidth, cut.last.tile.in.chrom=FALSE)
```

Arguments

<code>seqlengths</code>	Either a named numeric vector of chromosome lengths or a Seqinfo object. More precisely, if a named numeric vector, it must have a length ≥ 1 , cannot contain NAs or negative values, and cannot have duplicated names. If a Seqinfo object, then it's first replaced with the vector of sequence lengths stored in the object (extracted from the object with the <code>seqlengths</code> getter), then the restrictions described previously apply to this vector.
<code>ntile</code>	The number of tiles to generate.
<code>tilewidth</code>	The desired tile width. The effective tile width might be slightly different but is guaranteed to never be more than the desired width.
<code>cut.last.tile.in.chrom</code>	Whether or not to cut the last tile in each chromosome. This is set to FALSE by default. Can be set to TRUE only when <code>tilewidth</code> is specified. In that case, a tile will never overlap with more than 1 chromosome and a GRanges object is returned with one element (i.e. one genomic range) per tile.

Value

If `cut.last.tile.in.chrom` is FALSE (the default), a [GRangesList](#) object with one list element per tile, each of them containing a number of genomic ranges equal to the number of chromosomes it overlaps with. Note that when the tiles are small (i.e. much smaller than the chromosomes), most of them only overlap with a single chromosome.

If `cut.last.tile.in.chrom` is TRUE, a [GRanges](#) object with one element (i.e. one genomic range) per tile.

Author(s)

H. Pagès, based on a proposal by M. Morgan

See Also

- [genomicvars](#) for an example of how to compute the binned average of a numerical variable defined along a genome.
- [GRangesList](#) and [GRanges](#) objects.
- [Seqinfo](#) objects and the `seqlengths` getter.
- [IntegerList](#) objects.
- [Views](#) objects.

Examples

```
## -----
## A. WITH A TOY GENOME
## -----

seqlengths <- c(chr1=60, chr2=20, chr3=25)

## Create 5 tiles:
```

```

tiles <- tileGenome(seqlengths, ntile=5)
tiles
elementNROWS(tiles) # tiles 3 and 4 contain 2 ranges

width(tiles)
## Use sum() on this IntegerList object to get the effective tile
## widths:
sum(width(tiles)) # each tile covers exactly 21 genomic positions

## Create 9 tiles:
tiles <- tileGenome(seqlengths, ntile=9)
elementNROWS(tiles) # tiles 6 and 7 contain 2 ranges

table(sum(width(tiles))) # some tiles cover 12 genomic positions,
# others 11

## Specify the tile width:
tiles <- tileGenome(seqlengths, tilewidth=20)
length(tiles) # 6 tiles
table(sum(width(tiles))) # effective tile width is <= specified

## Specify the tile width and cut the last tile in each chromosome:
tiles <- tileGenome(seqlengths, tilewidth=24,
# cut.last.tile.in.chrom=TRUE)
tiles
width(tiles) # each tile covers exactly 24 genomic positions, except
# the last tile in each chromosome

## Partition a genome by chromosome ("natural partitioning"):
tiles <- tileGenome(seqlengths, tilewidth=max(seqlengths),
# cut.last.tile.in.chrom=TRUE)
tiles # one tile per chromosome

## sanity check
stopifnot(all.equal(setNames(end(tiles), seqnames(tiles)), seqlengths))

## -----
## B. WITH A REAL GENOME
## -----

library(BSgenome.Scerevisiae.UCSC.sacCer2)
tiles <- tileGenome(seqinfo(Scerevisiae), ntile=20)
tiles

tiles <- tileGenome(seqinfo(Scerevisiae), tilewidth=50000,
# cut.last.tile.in.chrom=TRUE)
tiles

## -----
## C. AN APPLICATION: COMPUTE THE BINNED AVERAGE OF A NUMERICAL VARIABLE
## DEFINED ALONG A GENOME
## -----

```

```
## See '?genomicvars' for an example of how to compute the binned  
## average of a numerical variable defined along a genome.
```
